22 **Running title:** Kin selection on leks

23

24 **Abstract**

25 In group living species, individuals may gain the indirect fitness benefits characterising
26 kin selection when groups contain close relatives. However, tests of kin selection have
27 primarily focused on cooperatively breeding and eusocial species, whereas its
28 importance in other forms of group living remains to be fully understood. Lekking is a
29 form of grouping where males display on small aggregated territories, which females
30 then visit to mate. As females prefer larger aggregations, territorial males might gain
31 indirect fitness benefits if their presence increases the fitness of close relatives. Previous
32 studies have tested specific predictions of kin selection models by using measures such
33 as group-level relatedness. However, a full understanding of the contribution of kin
34 selection in the evolution of group living requires estimating individuals' indirect fitness
35 benefits across multiple sites and years. Using behavioural and genetic data from the
36 black grouse (*Tetrao tetrix*), we show that the indirect fitness benefits of group
37 membership were limited because newcomers joined leks containing few close relatives
38 who had limited mating success. Males' indirect fitness benefits were higher in yearlings
39 during increasing population density but overall remained small and only marginally
40 changed the variation in male fitness. Kin selection acting through increasing group size
41 has a limited influence on male fitness and is therefore unlikely to contribute
42 substantially to the evolution and maintenance of lekking in this black grouse population.
43

44 **Introduction**

45 Group living is widespread in animals and may take many different forms, with
46 individuals associating with conspecifics in a range of temporal (short-term to life-long)
47 and spatial associations (Krause & Ruxton 2002). Irrespective of the degree of spatial
48 and temporal proximity, group living is often associated with substantial fitness benefits
49 such as reduced predation risks, enhanced foraging efficiency, alloparental care or
50 cooperation (Emlen 1995; Krause & Ruxton 2002; Clutton-Brock 2002). But in addition to
51 these direct fitness benefits, individuals may also gain indirect fitness benefits from living
52 in groups when closely related individuals live together (Kokko et al. 2001; Clutton-Brock
53 et al. 2002; Hatchwell 2010) meaning that kin selection might be involved in the
54 evolution of group living (Hamilton 1964; Griffin & West 2002; Grafen 2006). However,
55 most studies aiming at determining the role of kin selection in shaping specific
56 behaviours in species other than eusocial insect have focused on testing predictions of
57 kin selection models using measures such as group level relatedness (Reeve et al.
58 1990; McDonald & Potts 1994; Peters et al. 1999) or the modulation of behaviours
59 according to the relatedness of the interacting individuals (Ligon & Ligon 1978; Emlen &
60 Wrege 1988; Komdeur 1994; Russell & Hatchwell 2001). Therefore, actual
61 quantifications of the indirect fitness benefits associated with individuals' action are still
62 scarce (e.g. Creel & Waser 1994; Krakauer 2005; Gorrell et al. 2010; Hatchwell et al.
63 2014), despite them being necessary to compare individual's direct and indirect fitness
64 benefits and hence better understand the relative contribution of kin selection to the
65 evolution of the wide range of forms of group living observed in nature.

66 Lekking is a taxonomically widespread form of grouping in which males
67 aggregate on specific locations during the breeding season to acquire and defend a
68 small territory (Höglund & Alatalo 1995). Females visit the leks for the sole purpose of
69 mating and male mating success is highly skewed (Bradbury 1981; Kokko *et al.* 1999).

70 Leks have become a model for the benefits of group living driven by sexual selection
71 (Höglund & Alatalo 1995) and four non-mutually exclusive hypotheses have been
72 proposed to explain their evolution through increased male direct fitness: (i) increased
73 likelihood of encountering females by displaying where female density is high (Bradbury
74 *et al.* 1986); (ii) increased likelihood of encountering females by displaying close to an
75 attractive male (Beehler & Foster 1988); (iii) increased mating success through female
76 preference for large aggregations (Bradbury 1981); (iv) reduced predation risk in larger
77 aggregations (e.g. Boyko *et al.* 2005). However, males may also gain indirect fitness
78 benefits of group membership. This is because female preference for larger
79 aggregations (Isvaran & Pongshe 2013) means that males joining a lek with close
80 relatives may increase the fitness of close relatives (Kokko & Lindström 1996). Since the
81 vast majority of males have zero mating success (Kokko *et al.* 1999a; Höglund &
82 Lundberg 1987; Partecke *et al.* 2002), our understanding of the evolution and
83 maintenance of lek-display based upon the extreme male mating skew might be biased
84 if unsuccessful males gain substantial indirect fitness benefits.

85 Several studies have attempted to determine whether kin selection contributes to
86 the evolution of leks by measuring relatedness across lekking males (Supporting Table
87 S1) with the underlying assumption that males' indirect fitness benefits are low if the
88 average relatedness across lekking males is null. However, mean relatedness at the lek-
89 level is a valid proxy of male indirect fitness benefits only in species where individuals
90 can switch between groups throughout their lives. This is not the case of many lekking
91 species since the choice of group membership occurs only once as males are faithful to
92 their group (Kokko & Lindström 1996). Hence the relatedness of males territorial for the
93 first time (newcomers) to the other group members should be considered to avoid mixing
94 individuals with fundamentally different motivations and fitness pay-offs. Moreover, the
95 distribution of relatedness across lekking males is often bimodal with many unrelated

96 males and a few closely related individuals (e.g. Shorey *et al.* 2000). Therefore, although
97 the mean relatedness across lekking males is not significantly different from zero,
98 newcomers may gain substantial indirect fitness benefits if they are closely related to the
99 dominant male(s) of the lek. Furthermore, individuals' indirect fitness benefits are often
100 context-dependence (Rodrigues & Gardner 2012) as many ecological and individual
101 factors shape individuals' dispersal decision (Emlen 1982; Hatchwell & Komdeur 2000)
102 and hence the likelihood of encountering close relatives (see e.g. Piertney *et al.* 2008;
103 Koenig *et al.* 2011). Therefore, there might be considerable intra- and interspecific
104 variation in the mean relatedness across lekking males (Supporting Table S1) which
105 directly influences the magnitude of kin selection. Finally, lekking is a form of grouping
106 that is primarily driven by sexual selection (Höglund & Alatalo 1995) and the interaction
107 of group members may influence their fitness via increased mating success (Kokko &
108 Linström 1996). Therefore, better understanding the role of kin selection in the evolution
109 of lekking requires quantifying the relative contribution of individuals' direct and indirect
110 fitness benefits to the overall variation in mating success which quantifies the magnitude
111 of sexual selection. Hence, despite considerable previous efforts, previous studies have
112 only implied that kin selection on leks might occur (Petrie *et al.* 1999; Höglund *et al.*
113 1999; Shorey *et al.* 2000) but there is a clear need for studies that quantify the indirect
114 fitness benefits of male display, identify the factors underpinning the magnitude of
115 individuals' indirect fitness benefits, and compare the relative contributions of direct and
116 indirect components of sexual selection.

117 We used long-term data collected in a population of black grouse (*Tetrao tetrix*)
118 in Central Finland to quantify the indirect fitness benefits of group membership. The
119 black grouse is a classical lekking species in which male-male competition is direct
120 (Hämäläinen *et al.* 2012) and males are faithful to their lek site (Kokko *et al.* 1999b).
121 Previous studies have shown that black grouse males maximize their direct fitness

122 benefit by choosing a lek site according to their competitive ability (Alatalo *et al.* 1992),
123 and gain future direct benefits (Kokko *et al.* 1999b). However, the role of kin selection in
124 the formation of leks in this species is unclear because kin structures have not been
125 consistently found (Höglund *et al.* 1999; Lebigre *et al.* 2008). Genetic and detailed
126 behavioural observations over multiple consecutive years enabled us to identify
127 newcomers and measure their relatedness to the other lekking males. Here, we first
128 show how newcomers' indirect fitness benefits can be quantified as the product of (i) the
129 relatedness of the newcomers to the other lekking males with (ii) the effect of the
130 newcomers' presence on the mating success of the other lekking males (i.e. the
131 difference between the mating success of the other lekking males measured in the
132 presence and absence of the focal newcomers). We then test the hypothesis that such
133 indirect fitness benefits are context-dependent by measuring the effect of population
134 density, newcomers' age and lek site on the newcomers' indirect fitness benefits. Finally,
135 we quantify the contributions of the direct and indirect mating success to the variance in
136 newcomers' mating success to determine the contribution of kin selection acting through
137 increasing group size to the variance in newcomers' fitness.

138

139 ***Materials and Methods***

140

141 *Study population and field methods*

142 Individual black grouse were captured near Petäjävesi (Central Finland) at five study
143 sites during 2001-2007 (Kummunsuo, Lehtosuo, Saarisuo, Teerijärvensuo, and
144 Valkeissuo). Birds were captured using walk-in traps baited with oat seeds. All captured
145 birds were aged as yearling or older according to plumage characteristics and marked
146 with an aluminum ring and a unique combination of colour rings. Lek observations were
147 carried out from hides every morning throughout the mating season (end of April-early

148 May). Females mate once with a single male; male mating success was estimated from
 149 observed copulations as the sire of the broods nearly always matched behavioural
 150 observations (Lebigre *et al.* 2007). Males were defined as territorial when present on
 151 leks for at least 30% of the number of observations of the most attending male (Kervinen
 152 *et al.* 2012). Newcomers were identified when captured as one year old (yearling) and
 153 subsequently becoming territorial for the first-time on the studied leks. When full-siblings
 154 joined the same leks simultaneously, one male of each pair was retained in the analyses
 155 to avoid pseudoreplication (n = 11).

156

157 *Estimating newcomers' indirect fitness benefits*

158 The relationship (β) between the total number of copulations observed on any given lek
 159 (c_z , z denotes each lek site) and lek size (l_z) can be used to estimate the total number of
 160 copulations expected to occur on each lek had a newcomer not joined a specific lek ($c'_z =$
 161 $c_z - \beta$). The mating success of each male on a lek without the newcomer ($m'_{z,j}$, j denotes
 162 the focal male) can then be calculated as the product of c'_z by the contribution of
 163 individual j to c_z (i.e. $m'_{z,j} = (m_{z,j} / c_z) \times c'_z$). The difference between the mating success of
 164 each males' with and without the newcomer ($m_{z,j} - m'_{z,j}$) measures the increase in each
 165 male's mating success due to the presence of the newcomer. The indirect fitness
 166 benefits of a newcomer "i" on lek "z" ($w_{z,i}$) can therefore be estimated as (Eq. 1):

167
$$w_{z,i} = \sum_j^{N-1} R_{z,ij} \times [m_{z,j} - ((m_{z,j} / c_z) \times c'_z)]$$

168 where "N" is the size of lek "z", $R_{z,ij}$ the relatedness between the newcomer "i" and the
 169 other lekking males "j", and " $m_{z,j} - ((m_{z,j} / c_z) \times c'_z)$ " is the increase in the other lekking
 170 males' mating success due to the presence of the newcomer. This method may be
 171 applied in other contexts to estimate indirect fitness benefits when individuals' fitness

172 increases with group size (Krause & Ruxton 2002), and genetic data are available to
173 measure the relatedness of group members.

174 Eq. 1 estimates male indirect fitness benefits in terms of mating success as the
175 increasing group size leads to increasing mating success (Kokko & Lindström 1996).
176 However, male mating success might only be weakly related to their reproductive
177 success (i.e. number of offspring produced) if there is a mismatch between observed
178 mountings and genetic paternity. In black grouse, broods sired by multiple males are
179 very rare (Lebigre et al. 2007), parentage analyses nearly always matched lek
180 observations (Lebigre et al. 2007), and the variation in female clutch size is small (Table
181 2 in Ludwig et al. 2010). Therefore, mating success is a key fitness component in male
182 black grouse and its variation likely reflects the variation in male reproductive success.

183 An assumption of Eq. 1 is that the share of the total number of observed
184 copulations does not change with lek size which contradicts the commonly observed
185 increase in mating skew with decreasing leks size (Kokko *et al.* 1999a; Alatalo *et al.*
186 1992). Accounting for such effect would require reallocating fractions of some males'
187 mating success to others. However, three measures of variation (two measures of
188 skewness and the variance) were not related to lek size (Supporting Table S2).
189 Therefore, correcting for such effect is virtually impossible as it would require accounting
190 for changes in some but not all measures of variation with lek size. Besides, multiple
191 factors underpin the variation in male mating success in black grouse (see e.g.
192 Rintamäki *et al.* 2001; Kervinen *et al.* 2012) and two of these traits are expected to
193 change when a focal newcomer is taken out of a group: male territory positions (Hovi *et*
194 *al.* 1994) and male-male interactions (Hämäläinen *et al.* 2012). Given the complex
195 nature of the changes in the variation in male mating success with lek size and the lack
196 of biological background upon which we could define accurately the males gaining or

197 losing mating success, we decided not to reallocate mating success among males with
198 the disappearance of a specific individual.

199

200 *Relatedness and kinship estimates*

201 Genomic DNA was extracted from blood samples and all birds were genotyped at 11
202 highly polymorphic microsatellite loci (Lebigre *et al.* 2007). The relatedness among
203 individuals (R_{QG}) was calculated using RELATEDNESS 5.0.8 (Queller & Goodnight
204 1989) as described in Lebigre *et al.* (2008). There was no significant difference between
205 observed and expected R_{QG} values for full-siblings, half-siblings, and unrelated
206 individuals and parent-offspring relationships were slightly underestimated (Lebigre *et al.*
207 2010). In addition to R_{QG} , we also used the kinship coefficient (k) from the reconstruction
208 of a pedigree (Lebigre *et al.* 2010). The pedigree was reconstructed by first using
209 maximum the likelihood parentage assignments implemented in CERVUS 3.0
210 (Kalinowski *et al.* 2007). This allowed us to identify parent-offspring ($k = 0.5$) and some
211 full- and half-siblings relationships when individuals shared both or one parent ($k = 0.5$
212 and 0.25 respectively). Additional close kinships (full- and half-siblings) were then
213 identified using the group likelihood method implemented in COLONY v2.0 (Wang 2004;
214 Wang & Santure 2009). These additional kinships were accurate for full-siblings and
215 unrelated individuals (Type I error: 0.08 and 0.20 respectively; Type II errors: 0.19 and
216 0.10 respectively; see Lebigre *et al.* 2010). The error rate was higher for half-siblings
217 (Type I: 0.12; Type II: 0.55). To limit the risks of wrongly identifying unrelated dyads as
218 close relatives, the dyads of full- and half-siblings were therefore kept only if $R_{QG} > 0.2$
219 (Lebigre *et al.* 2010).

220

221 *Statistical analyses:*

222 We first used lek observations collected during 2001-2011 to quantify the effect of
223 increasing lek size on the total number of copulations. The linear mixed effect model to
224 quantify this effect was implemented in the r-package *nlme* (Pinheiro *et al.* 2013) with lek
225 site identity included as a random variable to account for the non-independence of
226 multiple observations of the same lek. The effect of year explained very little additional
227 variation and was therefore excluded of the final model. The variance structure of the
228 model was modified to account for heteroscedasticity (Pinheiro & Bates 2002).

229 We tested whether the magnitude of newcomers' indirect fitness benefits was
230 context-dependent by quantifying the effect of population density, the age of the
231 newcomers (yearling or older), and the lek site on newcomers' indirect fitness benefits.
232 These variables were chosen because it has been previously shown that population
233 density influences male lekking behaviour and lek size (Kervinen *et al.* 2012) and might
234 underpin changes in local kin structures due to changes in recruitment rate and adult
235 survival (see e.g. Piertney *et al.* 2008). Population density was estimated using wildlife
236 triangles censuses carried out in the previous autumn (Kervinen *et al.* 2012). During
237 2001-2007, the population underwent a phase of low density, a rapid increase, and a
238 peak of high density (Kervinen *et al.* 2012). Because of unbalanced sampling of
239 newcomers' age, three levels of population density were defined (low: 2001-2005;
240 increasing: 2006; high: 2007). Newcomers' age was also included as a covariate
241 because yearlings may be more likely to display with their father and hence may gain
242 greater indirect fitness benefits than older newcomers. Finally lek site was set as a
243 covariate in the analyses since some sites have consistently high or low total number of
244 observed copulations. Full models containing all independent variables and the
245 interaction between population density and newcomers' age were subsequently
246 simplified using a backward stepwise procedure. Model selection was based on changes

247 in the models' sum of squares (ANOVA), and deviance (logistic regression, generalised
248 linear model) following the removal of a variable.

249 ANOVAs were fitted to newcomers' indirect fitness benefits measured using R_{QG}
250 and the heteroscedasticity was tested using Fligner's test. Since, the distribution of
251 newcomers' indirect fitness benefits measured using k was right skewed and zero-
252 inflated, this variable was modelled in two steps: (i) a logistic regression with the binary
253 dependent variable describing whether newcomers' had zero or non-zero indirect fitness
254 benefits, and (ii) a generalized linear model with a Gamma error distribution (inverse
255 link) across males having non-zero indirect fitness benefits.

256 To quantify the degree to which the indirect fitness benefits associated with male
257 display influenced the variation in male mating success, we first carried out a variance
258 decomposition. As mating success has both direct and indirect (i.e. kin selected)
259 components, and as the variance in any two random X and Y variable can be
260 decomposed as $\text{Var}(X+Y) = \text{Var}(X) + \text{Var}(Y) + 2\text{Cov}(X,Y)$, then the variance in male
261 mating success can be decomposed as the sum of the variance in its direct component
262 and the variance in its indirect component and twice the covariance between these two
263 components. These variances were standardised by the squared mean in mating
264 success meaning that these variances were expressed in terms of opportunity for sexual
265 selection (I_{SS} , Shuster & Wade 2003). All analyses were carried out in R version 2.15.0
266 (R Core Team 2012).

267

268 **Results**

269

270 *Lek size and the total number of copulations*

271 The total number of copulations observed on leks was strongly positively related to lek
272 size in black grouse (linear mixed effects model: $\beta = 1.75 \pm 0.25$ (SE), t -value = 6.95, P

273 < 0.001, Fig. 1). Therefore, if a specific newcomer would not have joined a lek, the
274 expected total number of copulations observed on any given lek would have decreased
275 on average by 1.75 copulations.

276

277 *Kinship and mating success of the newcomers and the other males*

278 The size of the studied leks varied substantially during 2001-2007, ranging from 3
279 to 37 territorial males (Supporting Table S2). During this period, a total of 104
280 newcomers were identified (range: 0-11), and all of them were either 1 or 2 years old
281 (hereafter “yearling” and “older”, $n_{\text{yearling}} = 61$, $n_{\text{older}} = 43$). Only 16% of the newcomers
282 displayed with their father and 27% with at least one full-sibling meaning that newcomers
283 joined leks comprising mainly unrelated males (84% of the R_{QG} newcomers-lekking
284 males were below 0.2; mean $R_{\text{QG}} \pm \text{SD} = 0.009 \pm 0.186$, $N = 1798$ pairwise R_{QG} across
285 104 newcomers, Fig. 2A). The close relatives of the newcomers had moderate mating
286 success (across the 173 males closely related to at least one newcomer: median mating
287 success = 1, IQR = 0-2, Proportion of males with zero mating success: 0.63, Fig. 2B). In
288 particular the mating success of the full- and half-siblings of the newcomers was very
289 low (full-siblings: median mating success = 0, IQR = 0-2, proportion with zero mating
290 success = 0.54, $n = 37$; Half-siblings: median mating success = 1, IQR = 0-2, proportion
291 with zero mating success = 0.51, $n = 135$), while the fathers of the newcomers had a
292 moderate-high mating success (median mating success = 6, IQR = 1-11.5, proportion
293 with zero mating success = 0.13, $n = 15$, Fig. 3B). The top males of each lek had low
294 relatedness to the newcomers (mean $R_{\text{QG}} \pm \text{SD} = 0.002 \pm 0.204$, $N = 98$; five newcomers
295 joined a lek with an unringed top males and one newcomer became the top male of a
296 lek) and only 5 newcomers were sons of the top males of the leks.

297

298 *Indirect fitness benefits: context-dependence and contribution to the variance in male*
299 *mating success*

300 When Eq. 1 was parameterized using R_{QG} or k , the indirect fitness benefits of
301 group membership across newcomers was very low, equivalent to *ca.* 4% of an own
302 copulation (Table 1a, Fig. 3A and B). Newcomers' indirect fitness benefits were
303 influenced by the interaction between newcomers' age and population density when
304 estimated using R_{QG} (Table 2a). This effect was due to the greater indirect fitness
305 benefits of yearling than two year old newcomers during the increasing phase of the
306 population density (Supporting Fig. S1). When indirect fitness benefits were estimated
307 using k , all considered factors (population density, study site, and the interaction
308 between newcomers' age and population density) influenced to some extent the
309 likelihood of gaining or not gaining indirect fitness benefits as; none of them could be
310 removed without significantly reducing the model fit (Table 2b). Across all newcomers,
311 mating success was low (Table 1a) with yearling newcomers having a significantly lower
312 direct mating success than older newcomers (Table 1b and 1c, Wilcoxon rank-test, $W =$
313 879.5 , $P < 0.001$, $n = 104$, Fig. 3C). Nevertheless, newcomers direct fitness benefits
314 were substantially greater than their indirect fitness benefits which contributed to *ca.* 1%
315 of the standardized variance in male direct and indirect mating success (Table 3).

316

317 ***Discussion***

318 Fully understanding the fitness consequences of group living requires direct measures of
319 individuals fitness and estimates of the effect of each individual's action on the fitness of
320 their close relatives (leading to indirect fitness benefits). In lekking species, newly
321 established territorial males (newcomers) are usually unsuccessful (Höglund & Alatalo
322 1995), but they may gain indirect fitness benefits by increasing the mating success of
323 close relatives displaying on the same lek (Kokko & Lindström 1996). Here, we show

324 that male indirect fitness benefits are very small in the black grouse because newcomers
325 joined leks holding few close relatives and because close relatives to the newcomers
326 generally had low mating success.

327 The lack of strong kin structures in black grouse and several other lekking bird
328 species (Supporting Table S1) may seem surprising given these species' extreme
329 mating skew (Kokko *et al.* 1999a), which combined with male philopatry in birds
330 (Greenwood 1980) should facilitate the formation of kin structures in males (Hamilton
331 1964). However, key differences in morphology and life histories (Paradis *et al.* 1998) or
332 landscape structures (e.g. Bélisle *et al.* 2001) may lead to substantial inter- and
333 intraspecific variation in natal dispersal which may dampen the formation of large kin
334 groups. Male natal philopatry has been confirmed in black grouse by radio tracking
335 (Caizergues & Ellison 2002; Warren & Baines 2002) and genetic studies (Höglund *et al.*
336 1999; Lebigre *et al.* 2008). But, the low genetic differentiation found among males in the
337 same study population (Lebigre *et al.* 2008) suggests that among lek gene flow is
338 substantial and that male may also disperse among leks. The likelihood of kin group
339 formation in lekking species might also be overestimated if there is a mismatch between
340 the observed large variation in male mating success and reproductive success. This
341 might be the case in systems where females mate with multiple males on multiple leks or
342 outside leks (Petrie *et al.* 1992; Lank *et al.* 2002), but it is unlikely in black grouse since
343 polyandry is rare and observations provide reliable estimates of male reproductive
344 success (Alatalo *et al.* 1996; Lebigre *et al.* 2007). Therefore, male dispersal and a low
345 recruitment rate (Ludwig *et al.* 2010) are the most parsimonious explanations for the lack
346 of strong kin structures in this black grouse population.

347 Key life-history traits such as clutch size or adult longevity are widely expected to
348 shape the evolution of sociality (Hatchwell & Komdeur 2000, Hatchwell 2009) because
349 they underpin the formation of kin groups. In black grouse, the most dominant black

350 grouse males rarely retain their dominant position and generally have one clear peak of
351 mating success at age 2-4 (Kokko *et al.* 1999b) meaning that sons may join their fathers'
352 lek after their age of peak mating success. A full and half-siblings have often the same
353 age (i.e. the vast majority of them will be hatched the year of their father's peak mating
354 success), they will often have an equally low likelihood of mating due to their limited lek
355 experience. Therefore, even if groups do comprise close relatives, individuals' indirect
356 fitness benefits might be limited if their kin have low reproductive prospects or if their
357 parents have short tenures of dominant positions.

358

359 *Context-dependence of newcomers' indirect fitness benefits*

360 Male indirect fitness benefits were primarily influenced by population density and
361 newcomers' age. Specifically, the interaction between age and population density was
362 significant when indirect fitness was estimated using R_{QG} and when the likelihood of
363 gaining indirect fitness benefits using k was considered. These effects were due to the
364 high indirect fitness benefits of yearling newcomers during the increasing phase of the
365 population density. Therefore, the high recruitment rates and survival probabilities of this
366 cohort during increasing density led to increased likelihood of displaying with a close
367 relative and hence increasing indirect fitness benefits as reported in other systems
368 (Piertney *et al.* 2008, Nussey *et al.* 2005). Previous studies have shown that ecological
369 conditions can lead to changes in individual behaviour (reviewed in Hatchwell 2009;
370 Lehmann & Rousset 2010), and our study shows that demographic changes can in turn
371 influence the magnitude of individuals' indirect fitness benefits. Therefore, the indirect
372 fitness benefits of group membership are context-dependent but in spite of this variation
373 their overall magnitude remains small.

374

375 *Conclusions*

376 Fully understanding the role of kin selection in the evolution of any trait requires
377 quantifying all indirect effects associated with this trait. In this study, we quantified one of
378 these indirect effects and found that in black grouse there was a small positive indirect
379 fitness benefit gained through increasing lek size. These should be discounted by the
380 indirect fitness benefits which would have been gained had the newcomer joined another
381 lek and the indirect costs due to kin competition (Maynard Smith 1964; Griffin & West
382 2003) which are difficult to quantify with our current data. Marked males are very rarely
383 resighted far from the study sites. Therefore, they were unable to join the other leks used
384 in this study (distant of 9-36km) and a detailed observations of the territorial males
385 displaying on leks located in the vicinity of the studied sites is needed to estimate the
386 indirect fitness benefits a specific newcomer would have gained had he joined another
387 lek. Quantifying the magnitude of kin competition requires detailed information of the
388 fitness costs of lekking with close relatives. While the lek display is energetically costly to
389 all males in black grouse (Lebigre *et al.* 2013) and results in substantial fitness costs to
390 yearling newcomers (Siitari *et al.* 2007), these data cannot be used to estimate the
391 fitness costs of lekking with close relatives as unmanipulated black grouse choose
392 where and when they join leks according to their current body condition (Alatalo *et al.*
393 1992; Hovi *et al.* 1994; Kervinen *et al.* 2012) and may modulate their behaviour
394 according to their kinship to minimise these fitness costs (see e.g. Reynolds *et al.* 2012).
395 Therefore, additional analyses are needed to fully quantify the magnitude of the indirect
396 effects associated with group display in lekking species.

397 Sexual selection is clearly the main factor driving the evolution and maintenance
398 of group displays such as the leks (Höglund & Alatalo 1995), but the influence of kin
399 selection on the relationship between group size and mating success has never been
400 previously quantified. This study is the first to unequivocally show that the direct mating
401 success of males joining leks far outweighs the indirect fitness benefits gained through

402 increasing group size. Therefore, male indirect fitness benefits are solely context-
403 dependent by-products of male group display and kin selection is very unlikely to
404 contribute substantially to the maintenance of male aggregations in this black grouse
405 population.

406

407 ***Acknowledgments:***

408 This paper is dedicated to Prof. Rauno Veli Alatalo who passed away on November 9th
409 2012. We are grateful to Jon Slate, Andy Gardner, Graeme Ruxton, Paul Eady, and one
410 anonymous reviewer for comments on previous drafts of the manuscript. This work was
411 carried out with the permission of Central Finland Environmental Centre and the Animal
412 Care Committee of the University of Jyväskylä (permissions KSU-2003-L-25/254 and
413 KSU-2002-L-4/254).

414

415 ***Electronic Supplementary Material***

416

417 **Supporting Table S1.** Studies testing the potential for kin selection in lekking species.
418 Dashes indicate unknown value. Studies with multiple entries reported both significantly
419 positive and non-significant average relatedness across lekking males.

420

421 **Supporting Table S2.** Spearman rank correlation coefficients between lek size and
422 several measures of variation in male mating success.

423

424 **Supporting Table S3.** Variation in lek size across during 2001-2007. Values in
425 parentheses are the number of newcomers (yearling and older) identified on each lek in
426 each year.

427

428 **Supporting Figure S1.** Influence of population density and male age on the newcomers'
429 indirect fitness benefits. Newcomers' indirect fitness benefits were estimated here using
430 Queller and Goodnight's estimator (R_{QG}). The effect of population density on
431 newcomers' indirect fitness benefits are showed for yearling (black dots, solid lines) and
432 older newcomers (open dots, dashed lines).

600 **Data accessibility**

601 All pairwise relatedness between newcomers and the other lekking males and the
602 mating success of each male are described in the dryad repository
603 doi:10.5061/dryad.5d81k.

604 Input file for the relationship between lek size and the total number of copulation can be
605 retrieved in the dryad repository doi:10.5061/dryad.5d81k

606

607 **Author contributions:** CL and RVA derived eq.1, RVA CL and HS collected the data,
608 CL and CDS analysed the data, CL wrote the manuscript and all co-authors contributed
609 substantially to revisions. Authors sequence determines their contribution.

610 **Figure legends:**

611 **Figure 1.** Relationship between lek size and the total number of copulations observed in
612 any given lek. The line represents the predicted values of the linear mixed effect model.

613

614 **Figure 2.** Distribution of the relatedness between newcomers and the other lekking
615 males (panel A) and the distribution of the mating success the lekking males closely
616 related to at least one newcomer (panel B). Relatedness was estimated using Queller
617 and Goodnight's estimator (R_{QG}). The insert shows the distribution of the mating success
618 of the newcomers' fathers.

619

620 **Figure 3.** Distributions of the newcomers' indirect (panels A and B) and direct mating
621 success (panel C). The indirect fitness benefits were estimating by multiplying the
622 coefficient of kinship (k , panel A) or relatedness (R_{QG} , panel B) to the expected mating
623 success of the other lekking males, had the newcomer not been present. White and
624 black bars in panel C represent the direct mating success of yearling and older
625 newcomers respectively.

626 **Table 1.** Summary statistics of the indirect and direct mating success of the newcomers to a lek. Statistics are presented across a)
 627 all males, b) yearling newcomers (1 year old), and c) older newcomers (> 1yr old). Two measures of relatedness were used: the
 628 kinship between individuals and Queller and Goodnight's estimator of relatedness (R_{QG}). Non explicit table entries are: proportion of
 629 males with zero mating success (prop. zeroes), median (med.) interquartile range (IQR) and standard deviation (SD).
 630

	Indirect mating success						Direct mating success		
	Kinship			R_{QG}			Prop. Zeroes	Med.	IQR
	Prop. Zeroes	Med.	IQR	Mean	SD	IQR			
a) Overall (N = 104)	0.36	0.04	0.00-0.11	0.02	0.20	-0.12-0.15	0.68	0	0-1
b) Yearling males (n = 61)	0.30	0.04	0.00-0.15	0.04	0.21	-0.09-0.16	0.82	0	0-0
c) Older males (n = 43)	0.44	0.03	0.00-0.08	-0.01	0.18	-0.12-0.11	0.49	1	0-2

631

632 **Table 2.** Most parsimonious models explaining the variation in newcomers' indirect fitness benefits estimated using two measures of
633 relatedness; kinship coefficient (k) and Queller and Goodnight's estimator of relatedness (R_{QG}). Non explicit table entries: sample
634 size (N), degrees of freedom (df), F values for ANOVAs and Residual Deviance for logistic regressions (F / Res. Dev.), P -value (P),
635 difference in the degrees of freedom during model selection ($df2-df1$), F value of the changes in sum of squares (ANOVA) or
636 deviance (Logistic regression, generalised linear model), P -value of the stepwise backward selection method.
637

Indirect mating success	Model type	N	Independent variables	Omitted terms	df	F / Res. Dev.	P	$df2-df1$	F (SS/Deviance)	P_{back}
a)	Relatedness (R_{QG})	104	Density		2	0.87	0.42			
			Age		1	1.66	0.20			
			Age:Density		2	5.07	<0.01			
			Site		-	-	-	-4	0.80 (-0.12)	0.53
b)	Kinship (k , binary)	104	Density		2	129.01	0.04			
			Age		1	125.88	0.08			
			Site		4	117.66	0.08			
			Density:Age		2	110.09	0.02			
c)	Kinship (k , only if >0)	66		Density				-2	1.98 (-3.82)	0.14
				Age				-1	1.69 (-1.50)	0.19
				Site				-4	1.60 (-4.97)	0.19
				Density:Age				-2	0.40 (-0.63)	0.67

638 **Table 3.** Relative contributions of direct (D) and indirect (I) components to the variance
639 in mating success across newcomers. Both the kinship between individuals (k) and
640 Queller and Goodnight's estimator of relatedness (R_{QG}) were used as measures of
641 relatedness. Abbreviations are standardised variance in male mating success (I_T the
642 sum of newcomers' direct and indirect mating success), standardised variances in male
643 direct mating success (I_D), standardised variances in male indirect mating success (I_I),
644 covariance between newcomers' direct and indirect mating success ($cov_{D,I}$). Values in
645 parenthesis indicate the ratio of the standardised (co)variance of each component to I_W .
646

	K	R_{QG}
a) I_T	3.40	3.93
b) I_D	3.45 (1.01)	3.95 (1.01)
b) I_I	0.02 (0.01)	0.05 (0.01)
c) $2 * cov_{D,I}$	-0.06 (-0.02)	-0.08 (-0.02)
