Abstract: There is a desire to design lightweight railway vehicle bodies for future high speed trains. Previously, suppression of structural vibration of the flexible lightweight vehicle body was attempted via use of active suspensions (conventional actuators) or by structural damping via piezoelectric actuators, with the aim being to improve the ride quality. In a railway vehicle the typical active suspension setup comprises front and rear suspension conventional actuators, while adding more macro-actuator elements to minimise structural vibrations can substantially impact vehicle weight and location considerations. In this paper, we show that piezoelectric actuator control can provide complementary action to active suspensions. Decentralized control is adopted for combined active structural damping and active suspension design via Linear Quadratic Gaussian (LQG) method and modal control with skyhook damping respectively. The side-view model of a flexible-bodied railway vehicle integrated with piezoelectric actuators and appropriate sensor outputs is derived and the placement of the piezoelectric actuators and sensors is addressed via structural norms. It is shown that vibrations of both the flexible modes and rigid modes are suppressed effectively. This suggests that with the combined approach, control by both piezoelectric actuators and suspension actuators could be used in a more efficient way to address vibrations in light railway vehicle bodies.

Key Words: Railway vehicles, piezoelectric actuators and sensors, active structural damping, active suspension, LQG, Skyhook damping

1 Introduction

Future railway vehicles are tend to be designed lighter in order to achieve higher speed and also to be more cost-effective and energy-efficient. However, lightweight vehicle bodies are more flexible with structural vibration easily excited by exogenous disturbances, resulting in increased levels of high frequency vibration. Therefore, suppression of vibration of flexible modes besides the rigid modes of the vehicle body is required in order to improve ride quality levels.

Active/semi-active secondary suspension is the effective conventional approach for vibration control of railway vehicles to improve ride quality. Active suspensions and semi-active suspensions were made more aware of the flexible modes and their effectiveness in reducing the structural vibrations of a vehicle body in [4, 5]. Foo and Goodall [2] placed a third actuator in addition to two secondary suspension actuators at the centre of the vehicle for reducing the effects of the first flexible mode of the vehicle body. However, it was shown that the dynamics of the real actuators (e.g. electro-hydraulic actuators) cause a degradation of ride quality at higher frequencies [12] and the suspension points are near the nodes of the first bending mode, which suggest its limitation in suppressing the flexible modes.

Structural damping was applied via the smart structure concept of integrating piezoelectric actuators into the flexible structure. Passive structural damping was designed via shunted piezoelectric elements by electric circuits to dissipate the vibration energy of vehicle body [7, 16]. Kamada

et al. [9] used piezoelectric stack transducers in shunt damping for vibration suppression of a railway vehicle. Active structural damping with piezoelectric actuators was applied by Kamada et al.[8], independent $\mathcal{H}_\infty$ controllers were designed for suppressing the first three flexible modes. Schandl et al.[14] attached to the structure piezoelectric stack actuators mounted in consols together with collocated sensor patches, designing state feedback controllers by pole placement with state estimators. In the work by Kozek et al.[11], collocated strain sensors and piezoelectric actuators were used to introduce force/moments pairs into the car body structure and robust $\mathcal{H}_\infty$ control was applied. Benatzky et al. [1] designed the controller using the μ -synthesis procedure for structural vibration control of a scaled metro vehicle with piezoelectric stack actuators and piezoelectric patch sensors. A better performance was achieved compared to pole-placement combined with Kalman-filter techniques. Kamada et.al [10] illustrated the effectiveness of combined piezoelectric actuators and linear actuators in suppressing both the rigid and flexible modes with decentralized $\mathcal{H}_\infty$ controllers.

Coupling exists between rigid modes and flexible modes [17] and piezoelectric actuators have limitations on the maximum force they can produce, thus it is important to consider suppression of rigid mode and flexible mode vibrations simultaneously. In this paper, we investigate the performance of active structure damping combined with active suspension control. First, the side-view model of a flexible-bodied railway vehicle with piezoelectric actuators and sensors is derived. Then the placement of actuators and sensors is

done according to H_2/H_∞ norms. With decentralized control structure, LQG control is applied for active structural damping and modal control with skyhook damping for active suspensions. It is shown that sub controllers work complementary to each other and vibration of both the rigid and flexible modes are suppressed effectively.

2 Modelling

2.1 Side-view model with rigid vehicle body

The dynamics of a real railway vehicle can be very complex with non-linearities and substantial coupling in certain modes. However, a linear time-invariant model can appropriately represent the real system for the railway suspensions over the required mode of operation. The mathematical model of the system is based on the side-view of a railway vehicle as shown in Figure 1 [2]. It is a simplified model with two wheel sets included instead of four as it is sufficient to address the time delay of input excitations from front to rear bogies.

Fig. 1: Sideview model of a typical high speed passenger railway vehicles

The system's degrees of freedom include the vehicle body's bounce and pitch, flexible modes of the vehicle body, bounce modes of the two bogie masses, and two modes associated with the internal dynamics of the air spring. The pitch angle is assumed small so that

$$Z_{3L} = Z_{3C} + L_c \Theta \quad (1)$$

$$Z_{3R} = Z_{3C} - L_c \Theta \quad (2)$$

Lagrangian equations are used to establish the equations of motion and the model is represented in state space form as follows

$$\dot{\mathbf{x}}_r = \mathbf{A}_r \mathbf{x} + \mathbf{B}_r \mathbf{u} + \mathbf{G} \mathbf{w} \quad (3)$$

where $\mathbf{u} = [U_L \ U_R]$ is the control input vector across the secondary suspension, $\mathbf{w} = [\dot{Z}_{0L} \ \dot{Z}_{0R}]$ is the track velocity(disturbance) input vector. $\mathbf{A}_r$, $\mathbf{B}_r$, and $\mathbf{G}$ are system matrix, force input matrix, and disturbance input matrix respectively. The system state vector $\mathbf{x}_r$ is set as

$$\mathbf{x}_r = [Z_{3C} \ \dot{\Theta} \ \dot{Z}_{1L} \ \dot{Z}_{1R} \ R_1 \ R_2 \ R_3 \ R_4 \ R_5 \ R_6] \quad (4)$$

where

$$\begin{aligned} R_1 &= Z_{3L} - Z_{1L} & R_2 &= Z_{3R} - Z_{1R} & R_3 &= Z_{2L} - Z_{1L} \\ R_4 &= Z_{2R} - Z_{1R} & R_5 &= Z_{1L} - Z_{0L} & R_6 &= Z_{1R} - Z_{0R} \end{aligned} \quad (5)$$

2.2 Analytical model of flexible vehicle body with piezo-electric actuators and sensors

The flexible vehicle body is assumed a free-free Euler-Bernoulli beam of length, l , cross section area, A_b , mass M_b , material density, ρ_b and flexural rigidity, EI , which depends on the Young's modulus of elasticity E and the second moment of area I . The flexural vibration of the beam is induced by track disturbances transmitted through the suspensions. Stack piezoelectric actuators as shown in Figure 2 are integrated onto the vehicle body for suppressing the flexible modes. We choose this type of piezoelectric actuator because it is capable of introducing the necessary moments concerning the size, mass and stiffness of the structure[15].

Fig. 2: Piezoelectric actuator

The actuator expands when a voltage V_a is applied to it and actuation force F_p is generated when this expansion is constrained by mounting the actuator in a mechanical structure. It assumes that the equivalent actuation force is proportional to the applied voltage

$$F_p = A_p e_{33} \frac{V_a}{h_{st}} \quad (6)$$

where e is the piezoelectric coupling matrix, h_{st} is the thickness of one disk, and A_p is the area of cross section of the actuator.

Denote $z(x, t)$ the transverse deflection at point x of the beam and time t . The governing partial differential equations (PDEs) that describe the dynamics of the structure of the beam, assuming the beam is one-dimension only and has zero damping, is given as follows [6].

$$\begin{aligned} EI \frac{\partial^4 z(x, t)}{\partial x^4} + \rho_b A_b \frac{\partial^2 z(x, t)}{\partial t^2} &= \sum_{i=1}^{n_p} \frac{\partial^2 M_{px}(x, t)}{\partial x^2} \\ &+ F_{x_L}(t) \delta(x - l_1) + F_{x_R}(t) \delta(x - l_2) \end{aligned} \quad (7)$$

where F_{x_L} and F_{x_R} are the forces acting at the left and right suspension points. $i=1, 2, \dots, n_p$ denote the number of piezoelectric actuators, M_{px} is the moment acting on the beam by the piezoelectric actuators and is given by

$$M_{px}^i(x, t) = K_a V_{ai} [H(x - x_{1i}) - H(x - x_{2i})] \quad (8)$$

where V_{ai} is the voltage applied by the i th actuator. $H(\cdot)$ is the step function. x_{1i} and x_{2i} denote the location of the two ends of the i th piezoelectric actuator along the X axis, and K_a is a constant based on the properties of the beam and the piezoelectric actuators

$$K_a = \frac{A_p e_{33} d_p}{h_{st}} \quad (9)$$

where d_p is the vertical distance from the neutral axis of the vehicle body to the vertical centre of the piezoelectric actuator.

The end conditions for both free ends ($x = 0$ and $x = L_v$) of the beam are

$$\frac{\partial^2 z(x, t)}{\partial x^2} \Big|_{x=0} = \frac{\partial^3 z(x, t)}{\partial x^3} \Big|_{x=0} = 0 \quad (10)$$

$$\frac{\partial^2 z(x, t)}{\partial x^2} \Big|_{x=L_v} = \frac{\partial^3 z(x, t)}{\partial x^3} \Big|_{x=L_v} = 0 \quad (11)$$

By modal analysis technique, the solution of the transverse deflection $z(x, t)$ is assumed to be in the form

$$z(x, t) = z_{3c}(t) + \theta(t)(x - L_b/2) + \sum_{r=1}^{\infty} q_r(t) \phi_r(x) \quad (12)$$

where $q_r(t)$ is the r th flexible mode in the generalized coordinate and $\phi_r(x)$ is the corresponding mode shape, which is determined from the eigenvalue problem

$$\phi_r(x) = \frac{\cosh \lambda_r x + \cos \lambda_r x - \frac{\cosh(\lambda_r l) - \cos(\lambda_r l)}{\sinh(\lambda_r l) - \sin(\lambda_r l)}}{(\sinh(\lambda_r x) + \sin(\lambda_r x))} \quad (13)$$

The frequency equation of an undamped free-free beam is

$$\cos(\lambda_r l) \cosh(\lambda_r l) - 1 = 0 \quad (14)$$

through which, a series of λ_r can be determined, and the corresponding natural frequencies ω_r are determined by

$$\lambda^4 = \frac{\omega^2 A_b \rho_b}{EI} \quad (15)$$

Using solutions of Equations (13)-(15), the orthogonality properties of the mode shapes, and Dirac's delta function property

$$\int_{-\infty}^{\infty} \delta^{(n)}(t - \theta) \phi(t) dt = (-1)^n \phi^{(n)}(\theta) \quad (16)$$

where $\delta^{(n)}$ is the n th derivative of δ and ϕ is continuous at θ . Uncoupled ordinary differential equations representing the flexible motions of the beam can be obtained by integrating equation (7) over the beam length

$$\begin{aligned} \ddot{q}_r(t) + 2\zeta_r \omega_r \dot{q}_r(t) + \omega_r^2 q_r(t) &= \frac{K_a}{M_b} \sum_{i=1}^{n_p} \Psi_{ari} V_{ai}(t) \\ &+ \frac{F_{x_L} \phi_r(l_1)}{M_b} + \frac{F_{x_R} \phi_r(l_2)}{M_b} \end{aligned} \quad (17)$$

where structural damping is added and ζ_r is the damping ratio of the r^{th} flexible mode, and Ψ_{ari} is for the r th mode and i th piezoelectric actuator and is given by

$$\Psi_{ari} = \frac{d\phi_r}{dx}(x_{2i}) - \frac{d\phi_r}{dx}(x_{1i}) \quad (18)$$

The first flexible mode has shown the most significant influence on ride quality of the railway vehicle [2, 17]. For practical purposes only the first two flexible modes are considered in the model, and the corresponding mode shapes are shown in Figure 3. It is shown that each mode has its node points, i.e. where the corresponding mode shape is zero. The first flexible mode has its two node points near the positions

of the suspension points and the second flexible mode has its node point at the middle of the beam. According to the forcing terms at the right hand side of Equation [17], the absolute value of a mode shape at certain point is an evaluation of importance of the control force acting at that point and the absolute value of Ψ_{ari} at certain place is an evaluation of the importance of the i th piezoelectric actuator for the r th mode.

Fig. 3: Mode shapes of the free-free beam of a railway vehicle

Piezoelectric laminar sensors are bonded to the structure for measuring the flexible modes. They produce voltage signals proportional to the average curvature. They are advantageous when only the vibrations of the flexible modes have to be measured and the signal part of the rigid body modes has to be eliminated [1]. The induced voltage v_{pj} by the j^{th} piezoelectric sensor is given by [6]

$$v_{spj}(t) = K_s \sum_{r=1}^{\infty} \Psi_{rj} q_r(t) \quad (19)$$

where

$$\Psi_{srj} = \frac{d\phi_r}{dx}(x_{2j}) - \frac{d\phi_r}{dx}(x_{1j}) \quad (20)$$

where Ψ_{srj} is for the r th mode and j th piezoelectric sensor, and x_{1j} and x_{2j} denote the position of the two ends of the j th sensor. K_s is related to the properties of the sensor and the beam.

Transform the description of the flexible model by Equation (17) to the state-space form as follows

$$\begin{aligned} \dot{\mathbf{x}}_f &= \mathbf{A}_f \mathbf{x}_f + \mathbf{B}_{f1} \mathbf{u}_1 + \mathbf{B}_{f2} \mathbf{d} \\ \mathbf{y}_1 &= \mathbf{C}_v \mathbf{x}_f \end{aligned} \quad (21)$$

where the state vector $\mathbf{x}_f$ is chosen as

$$\mathbf{x}_f(t) = [\dot{q}_1(t) \quad q_1(t) \quad \dot{q}_2(t) \quad q_2(t)] \quad (22)$$

$\mathbf{u}_1$ is the $(n_p \times 1)$ vector of voltage inputs to the piezoelectric actuators, $\mathbf{d} = [F_{x_L} \ F_{x_R}]$ is the vector of force inputs from suspensions, $\mathbf{y}_1$ is the $(m_p \times 1)$ vector of measured variables by piezoelectric sensors, and input matrices and output ma-

trices are as following

$$\mathbf{B}_{f1} = \frac{K_a}{M_v} \begin{bmatrix} \Psi_{a11} & \Psi_{a12} & \cdots & \Psi_{a1n_p} \\ 0 & 0 & \cdots & 0 \\ \Psi_{a21} & \Psi_{a22} & \cdots & \Psi_{a2n_p} \\ 0 & 0 & \cdots & 0 \end{bmatrix} \quad (23)$$

$$\mathbf{B}_{f2} = \begin{bmatrix} \frac{\phi_1(x_L)}{M_v} & \frac{\phi_1(x_R)}{M_v} \\ 0 & 0 \\ \frac{\phi_2(x_L)}{M_v} & \frac{\phi_2(x_R)}{M_v} \\ 0 & 0 \end{bmatrix} \quad (24)$$

$$\mathbf{C}_v = \frac{K_s}{C_p} \begin{bmatrix} 0 & \Psi_{s11} & 0 & \Psi_{s21} \\ 0 & \Psi_{s12} & 0 & \Psi_{s22} \\ 0 & \vdots & 0 & \vdots \\ 0 & \Psi_{s1m_p} & 0 & \Psi_{s2m_p} \end{bmatrix} \quad (25)$$

2.3 The overall model

Combining the rigid model by Equation (3) and the flexible model by Equation (21), the overall model of the system in its state space form is given by

$$\dot{\mathbf{x}} = \begin{bmatrix} \mathbf{A}_r(12 \times 12) & \mathbf{A}_{fr}(12 \times 4) \\ \mathbf{A}_{rf}(4 \times 12) & \mathbf{A}_f(4 \times 4) \end{bmatrix} \mathbf{x} + \begin{bmatrix} \mathbf{B}_r \\ \mathbf{B}_{f1} \end{bmatrix} \mathbf{u} + \begin{bmatrix} \mathbf{0} \\ \mathbf{B}_{f2} \end{bmatrix} \mathbf{V}_a + \begin{bmatrix} \mathbf{G} \\ \mathbf{0} \end{bmatrix} \mathbf{w} \quad (26)$$

where

$$\mathbf{x} = [\mathbf{x}_r \quad \mathbf{x}_f] \quad (27)$$

and $\mathbf{A}_{fr}$ and $\mathbf{A}_{rf}$ are coupling matrices of the flexible and rigid states.

Based on the parameters given in [17], the bounce and pitch modes are at frequencies of 0.67Hz and 0.85Hz with damping ratios of 0.16 and 0.2 respectively and the first flexible mode is at 8.45Hz and the second flexible mode is around 23.2Hz.

2.4 Placement of piezoelectric actuators and sensors

$\mathcal{H}_2$ and $\mathcal{H}_\infty$ structural norms are used for evaluating the importance of actuators and sensors at their given positions. Here, we follow the approach in [3], where the norms of the r^{th} mode can be approximately determined by

$$\|G_r\|_2 \cong \frac{\|B_r\|_2 \|C_r\|_2}{2\sqrt{\zeta_r \omega_r}} \quad \|G_r\|_\infty \cong \frac{\|B_r\|_2 \|C_r\|_2}{2\zeta_r \omega_r} \quad (28)$$

And the $\mathcal{H}_2$ (or $\mathcal{H}_\infty$) norm of the r^{th} mode with a set of actuators/sensors is the rms sum of H_2 (or $\mathcal{H}_\infty$) norm of the mode with each single actuator/sensor.

$$\|G_r\|_2 \cong \sqrt{\sum_{i=1}^{n_p} \|G_{ri}\|_2^2} \quad \|G_r\|_\infty \cong \sqrt{\sum_{i=1}^{n_p} \|G_{ri}\|_\infty^2} \quad (29)$$

According to the definition of the structural norms and the input and output matrices in equations (23) to (25), it is preferable to place the piezoelectric actuators and sensors at positions where Ψ_{ari} and Ψ_{srj} have high absolute values. As shown in Figure 4, the norms reach maxima at $x=(13.5)$ for the first flexible mode and $x=7.84$ and $x=(19.16)$ for the second flexible mode.

Fig. 4: Normalized $\mathcal{H}_\infty$ (or $\mathcal{H}_2$) indices as a function of actuator location with fixed sensor

Therefore, as it is shown by Figure 5, piezoelectric stack actuators (20 in parallel in order to achieve the necessary moments) and patch sensor are placed at $x = (13.5)$ for suppressing the 1st flexible mode, and at $x = (7.84)$ and $x = (19.16)$ for suppressing the 2nd flexible mode.

Fig. 5: Configuration of piezoelectric actuators and sensors

3 Track profile and assessment method

The assessment of ride quality relates to vehicle running on straight track with vertical misalignments (irregularities). For secondary suspension assessment, Gaussian white noise with a flat spectrum is a good approximation for the track velocity inputs [13]

$$\dot{S}_T(\omega_t) = 2\pi\Omega_v v \quad (ms^{-1})^2(rad/s)^{-1} \quad (30)$$

where v is the velocity of the vehicle and Ω_v is the roughness factor, which is taken as 2.5×10^{-7} for a good quality mainline track. A delay of 0.35 s between the front and rear track inputs is included.

Root mean square (RMS) values of vertical accelerations of the vehicle body are used to quantify the ride quality, in this case without frequency weighting. Frequency domain techniques are used to obtain RMS values and the power spectral densities (PSDs) of the signals of interest including body accelerations ($\ddot{z}_{xL}$, $\ddot{z}_{xC}$ and $\ddot{z}_{xR}$) and suspension deflections ($z_{3L} - z_{1L}$ and $z_{3R} - z_{1R}$) in response to track irregularities.

4 Controller design

The controller design aims to reduce the vertical accelerations of the vehicle body while keeping the suspension deflections small. Hence a control law needs to be designed to determine the moments from the piezoelectric actuators and the forces from the active suspension actuators so that both the rigid mode and flexible mode vibration are suppressed.

Decentralize control strategy is adopted. Figure 6 shows the closed-loop system with structural damping controller

Fig. 6: Structure of decentralized control

K_1 and suspension controller K_2 . $G(s)$ represents the full model, $\mathbf{u}_1$ is piezoelectric actuator control input vector, $\mathbf{y}_1$ is measurements by the piezoelectric sensors, $\mathbf{u}_2$ is suspension control input vector, and $\mathbf{y}_2$ is measurement output vector of accelerations of the vehicle body.

4.1 Active structural damping with piezoelectric actuators and sensors

Linear Quadratic Gaussian (LQG) control is applied for the design $K_1(s)$. It aims to minimize the accelerations of flexible motion against disturbances. The flexible model (21) is used for control design.

Performance positions are chosen as the centre of the vehicle, x_C , left suspension point, x_L , and right suspension point, x_R . Accelerations of the flexible modes at the above three positions are chosen as the controlled variables.

$$\mathbf{y}_f = \begin{bmatrix} \phi_1(x_C)\ddot{q}_1 + \phi_2(x_C)\ddot{q}_2 \\ \phi_1(x_L)\ddot{q}_1 + \phi_2(x_L)\ddot{q}_2 \\ \phi_1(x_R)\ddot{q}_1 + \phi_2(x_R)\ddot{q}_2 \end{bmatrix} \quad (31)$$

The problem is to devise a feedback-control law which minimizes the cost

$$J = \lim_{T \rightarrow \infty} E \left\{ \int_0^T [\mathbf{y}_f(t)^T \mathbf{Q} \mathbf{y}_f(t) + \mathbf{u}^T(t) \mathbf{R} \mathbf{u}(t)] \right\} \quad (32)$$

where $\mathbf{R}_0$ is the input weighting matrix and its elements are fixed at 1. $\mathbf{Q}_y$ is the output weighting matrix and is chosen according to Bryson's rule [18]

$$\mathbf{Q}_y = \text{diag}\{1/(q_{y1})^2, 1/(q_{y2})^2, 1/(q_{y3})^2\} \quad (33)$$

where q_{y1} , q_{y2} and q_{y3} are initially given the expected values of the controlled variables and further tuned accordingly to achieve the best performance while maintaining the input voltages of the piezoelectric actuators within their limits.

Kalman filter is designed to estimate the states of the system that cannot be measured. The system is subject to disturbances from the secondary suspensions $\mathbf{d}$. The variance of the disturbance is obtained from the simulation results of the passive system of the railway system. Piezoelectric sensor patches measure the strain in the beam by feeding back voltage signals. The measurement noise is assumed to have a root mean square value of one percent of the maximum value measured by the sensors, however, is further tuned until the estimator can provide a good performance for the system.

4.2 Active suspension control

Modal control with skyhook damping is adopted for active suspension control. Figure 7 shows the structure of the

control system. Two linear accelerometers are used to measure vehicle body accelerations at the two suspension points, $\ddot{z}_{x_L}$ and $\ddot{z}_{x_R}$. The measured signals are decomposed into modal components (i.e. bounce $\ddot{z}_b$ and pitch $\ddot{z}_p$). Then the bounce and pitch modes are controlled separately with skyhook damping, and finally the modal control signals are recombined and feed to the actuators.

Fig. 7: Modal control with skyhook damping

Skyhook damping is a simple conventional method known to give sufficient improvements in ride quality of railway vehicles. The control action of an ideal skyhook damper is dependent upon the absolute velocity of a vehicle body.

$$F_b = -c_b \dot{z}_b \quad (34)$$

$$F_p = -c_p \dot{z}_p \quad (35)$$

where F_b and F_p are the modal control forces, c_b and c_p are the modal skyhook damping gains, and $\dot{z}_b$ and $\dot{z}_p$ are the absolute velocity of the bounce and pitch modes of the vehicle body. In practice, the acceleration of the vehicle body is measured and then the signal is integrated to get the absolute velocity. A high pass filter is used along with an integrator in order to eliminate the long-term drift caused by offset effect of the transducer due to environmental reasons. A second order Butterworth high-pass filter (HPF) is used

$$H_{hp} = \frac{s^2/\omega^2}{s^2/\omega^2 + s2\zeta/\omega + 1} \quad (36)$$

where the cut-off frequency ω is chosen to be significantly less than the main suspension frequency, and in this case is chosen to be 0.1Hz.

5 Simulation results and discussion

The results are based on the actuator and sensor specifications given in Appendix and vehicle parameters given in [17].

Figure 8-10 compare the PSDs of systems $G+K_1$, $G+K_2$ and $G+K_1+K_2$ in response to track irregularities. It is shown that the first flexible mode (around 8Hz) is the main cause of degradation of ride quality while the second flexible mode (around 23Hz) is as small as negligible. With controller K_1 , only the first flexible mode vibration is reduced. With controller K_2 , the rigid mode vibrations at frequencies < 1 Hz are substantially reduced while the first flexible mode vibration is only slightly reduced. With combined controller K_1+K_2 both the rigid and flexible mode vibrations

are reduced and the first flexible mode achieved a lower level of vibration than K_1 .

Figure 11 compares suspension control forces for cases $G + K_2$ and $G + K_1 + K_2$. Small reduction in the force inputs for $G + K_1 + K_2$ around the flexible mode frequencies are observed. Figure 12 compares between voltage inputs of piezoelectric actuator A1 for $G + K_1$ and $G + K_1 + K_2$. It is shown that, for $G + K_1 + K_2$, smaller efforts are demanded from the piezoelectric actuators than $G + K_1$, and the piezoelectric control efforts become more concentrated around the flexible mode frequencies. This suggests that more efficient control from piezoelectric actuators are achieved with combined approach $K_1 + K_2$.

Table 1 compares the RMS results between the passive system, closed-loop systems $G + K_1$, $G + K_{sky}$ and $G + K_1 + K_{sky}$ in response to vertical track irregularities. $G + K_1$ achieved substantial acceleration reduction at center of the vehicle x_c , while the accelerations at x_L and x_R are only slightly reduced. This is because the center acceleration is influenced the most by the first flexible modes. Significant reductions in all three accelerations are achieved by $G + K_2$, while the center acceleration is slightly higher than $G + K_1$. With $G + K_1 + K_2$, a further reduction in center acceleration is brought by piezoelectric actuators compared to $G + K_2$. However, both the suspension control forces and piezoelectric actuator voltages are reduced compared to $G + K_1$ and $G + K_2$ respectively. This also suggests that the combined approach helps to use the piezoelectric actuators and suspension actuators more efficiently to address the overall vibration issues.

6 Conclusion

Combined active structural damping and active suspension control is investigated for vibration control of typical flexible-bodied railway vehicles. The design is based on a simplified side-view model of the railway vehicle considering only the first two flexible modes. It is shown that combined active structural damping and active suspension control work more efficiently in a complementary manner to each other that both the rigid and flexible mode vibrations are suppressed effectively.

Appendix: Specifications of piezoelectric actuators and sensors

Table 2: Specification of piezoelectric stack actuator

Maximum force	50,000N
Length, L_{px}	0.194m
Thickness of one disk	5×10^{-4} m
Diameter of disk	0.045m
Piezoelectric constant, d_{33}	6.80×10^{-10} m/volts
Compliance, s_{33}^E	23×10^{-12} m ² /N

Table 3: Specification of piezoelectric sensor patch

Length	0.02 m
Thickness	2.5×10^{-4} m
Width	0.025 m
Young's Modulus, E_p	6.70×10^{10} N/m ²
Capacitance, C_p	1.05×10^{-7} F
Electromechanical coupling factor, k_{31}	0.34
Voltage constant, g_{31}	-1.15×10^{-2} Vm/N
