The influence of individual cognitive style on performance in management education

ABSTRACT

This paper reports the outcomes of an empirical study undertaken to explore the possibility that cognitive style may be an important factor influencing performance on certain types of task in management education. Four hundred and twelve final-year undergraduate degree students studying management and business administration were tested using the Allinson-Hayes Cognitive Style Index. Their cognitive styles were then compared with assessment grades achieved for academic modules, the task categories of which were deemed to be consonant with either the wholist/intuitive or the analytic style of working. Overall ability defined by final degree grades was also tested against individuals' cognitive styles. As expected, students whose dominant cognitive styles were analytic attained higher grades for long term solitary tasks involving careful planning and analysis of information. However, contrary to expectations, performance on tasks believed to be more suited to the wholist/intuitive style was also higher for analytic individuals, as was overall ability defined by final degree grades. The results were discussed in terms of the nature of the tasks and the need for methods of performance assessment that are independent of an orientation bias. Without this, it is argued, employment selection criteria may favour the wrong type of candidate in some circumstances.

Whether or not cognitive style is related to ability is unclear. However, what is clear from the evidence available is that difficulties arise in interpreting the relationship because of the confounding influence of the tasks selected to measure ability. In order to determine whether or not a relationship exists, it is first of all important to try to determine the characteristics that distinguish style from ability because both will affect performance on a given task. Witkin *et al* (1977) differentiate between the two by emphasising the bi-polar nature of cognitive styles, unlike intelligence or other abilities. They suggest that each pole of cognitive style has adaptive value under specified circumstances whereas to have more of an attribute such as intelligence is better than to have less of it. This difference has been very well defined by Riding (1996):

‘The basic distinction between them is that performance on all tasks will improve as ability increases, whereas the effect of style on performance for an individual will either be positive or negative depending on the nature of the task. It follows from this that for an individual at one end of the style dimension, a task of a type they find difficult will be found easier by someone at the other end of the dimension, and *vice versa*’ (p2).

This leads to the interesting possibility that cognitive style may be an important factor influencing performance on certain types of task. The purpose of this study was to determine whether or not a relationship did exist between individuals’ cognitive styles and their ability to perform well on tasks requiring different approaches to information gathering, processing and evaluation. The study also examined the relationship between cognitive style and overall ability.

Cognitive Style

An individual's cognitive style may be defined as a self-consistent mode of functioning which individuals show in their perceptual and intellectual activities (Witkin *et al*, 1971).

Goldstein and Blackman (1978) suggest that this relates to the characteristic and habitual way in which an individual processes and evaluates information, solves problems and makes decisions. Riding *et al* (1993) suggested that cognitive style differences may be due to differences in left/right hemispheric specialisation of the brain which is a commonly held view shared by other researchers in the field (Mintzberg, 1976; Ornstein, 1977; Doktor, 1978; Robey & Taggart, 1981; Agor, 1984; Taggart *et al*, 1985; Waber, 1989; Sonnier, 1990; Allinson & Hayes, 1996). This connection between neuro-physiology and cognitive psychology stems from the pioneering work of Sperry (1964), Luria (1966), Gazzaniga (1967) and Bogen (1969). Their studies demonstrated the human left cerebral hemisphere to be specialised for primarily analytic, rational and sequential information processing and the right cerebral hemisphere to be specialised for primarily intuitive, holistic, and simultaneous information processing. Whilst some now regard this split brain formulation as an oversimplification (Rao *et al*, 1992), others (e.g. Languis, 1998; Languis & Miller, 1992) continue to report patterns of brain mapping research which are consistent with Luria's (1980) theory of brain functioning. Irrespective of whether the left brain/right brain analogy is scientifically correct, it does nevertheless serve as a useful metaphor for describing these cognitive differences.

In a review of the literature, Armstrong (1999) identified 54 dimensions on which cognitive style has been differentiated. These include:

- Field dependence-field independence (Witkin *et al*, 1962).
- Reflective-impulsive (Kagan, 1965).
- Serialist-holist (Pask & Scott, 1972).
- Converger-diverger (Hudson, 1968).

- Simultaneous-successive (Das, 1988).
- Wholist-analytic (Riding, 1991).
- Leveller-sharpener (Holzman & Klein, 1954).

Although certain authors (e.g. Zelniker, 1989) argue that this multiplicity of constructs reflects the sheer complexity of cognition, others have suggested that they are merely different conceptions of a superordinate dimension (Messick, 1976; Kogan, 1983; Miller, 1987; Rayner & Riding, 1997). On this basis, Riding and Douglas (1993) defined a principal cognitive style group comprised of the dimensions listed above. They labelled these the Wholist-Analytic cognitive style. These poles are also commonly labelled Intuitive-Analytic (Zeleny, 1975; Doktor, 1978; Agor, 1986; Hammond *et al*, 1987; Allinson & Hayes, 1996)

In a work context, analytic individuals tend to be compliant, their thinking relies on logical sequences and vertical reasoning, they prefer structured approaches to decision making, apply systematic methods of investigation, and are especially comfortable when handling problems requiring a step by step solution. Wholist/intuitive individuals, on the other hand, would tend to be nonconformist, their thinking relies on impulsive synthesis and lateral reasoning, they prefer rapid, open-ended approaches to decision making, they rely on random methods of exploration and work best on problems favouring a holistic approach (Allinson, Armstrong & Hayes, *forthcoming*; Zeleny, 1975; Lynch, 1986).

Relationship Between Cognitive Style and Ability

In answer to the question of whether cognitive style is related to ability, several notable researchers have agreed that cognitive styles are different from intellectual abilities in multiple and important ways (Witkin *et al*, 1977b; Sharma, 1986; Keefe, 1988). Campbell (1991) shares similar views to Messick (1984) who believes that intellectual ability refers to

what kind of information is being processed by *what* operation, in *what* form and how well, whereas cognitive styles refer to the manner or mode of cognition - to the question of *how*.

However, as Miller (1987) observed, the relationship between style and ability continues to be a thorny problem in the cognitive style literature, one that is exemplified by the controversy over field dependence/independence (Witkin *et al*, 1971) and in particular the Group Embedded Figures Test (GEFT). A number of empirical studies using this test have suggested that cognitive style may be related to ability in some way. For example, it has been shown that field-independent children learn new computer languages more quickly and make less errors than their field-dependent counterparts (Watson & Brinkley, 1992; Easton & Watson, 1993; Cavaiani, 1989). Similar findings have been reported for abilities in the learning of language, (Jamieson, 1992), biological sciences (MacNab *et al*, 1991), mathematics (Van-Blerkom, 1988), mechanical drafting (Guster, 1986), and performance in multiple choice tests used to measure ability in a wide variety of subjects (Armstrong, 1993). Renninger and Snyder (1983) also found that field independent secondary students scored higher on standardised measures of academic ability. Some researchers have criticised the Field Dependence/Independence dimension for not actually measuring cognitive style (Guilford, 1970; Kagan, 1976) and it has been suggested that it may measure some component of cognitive ability instead (Kush, 1996; Sweiger, 1983; Goldstein & Blackman, 1978, p185; Flexer & Roberge, 1980). MacLeod *et al* (1986) attributed this to the degree of overlap between this dimension and the construct of spatial ability, which plays a key role in theories of intelligence. Riding and Pearson (1994) found some support for this in their investigations using the British Abilities Scale Short Form (Elliot, 1983) to measure intelligence. Whilst they found no significant relationship between cognitive style and intelligence using the Cognitive Styles Analysis instrument (Riding, 1991) they did find a relationship between intelligence and a Test of Embedded Shapes (Pearson, 1991) which is similar to GEFT.

But other measures have also revealed significant relationships between cognitive style and ability. Researchers using Kolb's (1976) Learning Styles Inventory, for example, have found that style influences academic performance in computer engineering (Sein & Robey, 1991), statistics (Hudak and Anderson, 1990), optometry (Sparks, 1990), business studies (Geiger, 1991) and numerical aptitude (Green and Parker, 1989). Furthermore, Letteri (1980) demonstrated how a cognitive profile could be mapped, using seven separate bi-polar dimensions, to significantly differentiate between high and low academic performers. High performers were characterised, according to the seven cognitive style dimensions, as being *analytical (field independent), focuser, narrow, complex, reflective, sharpener and tolerant*. Low academic performers were characterised as being *global (field dependent), nonfocuser, broad, simple, impulsive, leveller, intolerant*. Similar studies (e.g. Frederico & Landis, 1984) using multiple instruments to measure cognitive styles have also shown styles to be related to abilities and aptitudes. Whilst some researchers might agree with previous views (e.g. Vernon, 1972; Wardell & Royce, 1978) that measures of cognitive style therefore do not define a dimension distinct from general intelligence, it is important to consider that these studies do not adequately discuss the nature of the tasks used to measure ability. Because these may have favoured one cognitive style (e.g. analytic) over the other (e.g. wholist/intuitive), the question of whether these results support a link between styles and ability must again remain unanswered. Some authors (e.g. Globerson *et al*, 1985) have even suggested that controversies over the use of Field Dependence/ Independence instruments may be due to inappropriate selection of tests to measure ability,

'our findings seem to support the notion that the correlations between IQ and field dependence/independence reported in the literature may be due to incompatibility between the demands of a few sub-tests of the intelligence scale and the habitual information-processing strategies of the field dependent subjects' (p690).

In the context of the present study, the preceding discussions therefore highlight the importance of paying careful attention to the following points in order to minimise the effect of potentially confounding variables:

- Instruments for measuring cognitive style that are indexed by success in isolating a particular geometric pattern inside a larger pattern should be avoided due to a potential overlap with spatial ability and probably intelligence.
- The types of task used to evaluate subjects' ability/performance need to be considered carefully because these may favour one cognitive style over the other.

Research Hypotheses

There appears to be some evidence pointing to the possibility that instruments such as Witkin's GEFT (Streufert & Nogami, 1989; Widiger *et al*, 1980) and Kagan's MFFT (Streufert & Nogami, 1989) may measure some aspect of intelligence as well as cognitive style. However, we have seen that this distinction is often blurred and the overall balance of evidence suggests that the cognitive style construct, itself, and overall ability or intelligence are unrelated (Riding & Pearson, 1994). In the present study involving a sample of students in their final year of a Business Administration Degree, it is therefore hypothesised that *(Hypothesis 1) there will be no significant difference in overall degree grades for students who fall into either the wholist/intuitive category of cognitive style or the analytic category.*

One interesting possibility, however, is that cognitive style may be an important factor influencing performance on certain types of task. For example:

- (a) In a task requiring an individual to see a problem in its overall context in order to arrive at a balanced view from which he/she would make important decisions, wholist/intuitive types are likely to excel over analytics because the latter will be

more inclined to focus on one aspect of the overall situation to the exclusion of others. Similarly, in a situation where it is important to generate ideas rapidly, or where working with others is an important component in a decision making process, wholist/intuitive types are again likely to excel.

- (b) Conversely, where tasks require careful planning and analyses of information to solve detailed problems, or where logical, reflective and linear approaches are required for long term solitary tasks, analytical types are likely to excel over wholist/intuitives because of the difficulty they experience in separating-out a situation into its constituent parts.

This leads to the main research hypotheses that assessment grades achieved for academic modules deemed to be consonant with one, or other of the above categories will be dependent on individuals' cognitive styles. For example, one module requires the students to undertake a project the published criteria of which state that it must be an individual piece of research which is problem solving in nature, requiring detailed and systematic collection and analysis of secondary and primary data. The students must demonstrate synthesis and evaluation of solutions, and a logical and linear progression through careful planning and scheduling. This task, which culminates in the submission of an 8000-word dissertation after a project duration of eight months, is deemed to be consonant with the scenario defined under category (b) above. This leads to the hypothesis that (***Hypothesis 2***) *the more analytic a student's cognitive style, the higher will be his or her research project grade.*

Another module requires these students to undertake a unit of study in Business Policy and Strategy, the published learning aims of which require the students to synthesise issues relating to the global environment in order to understand the organisation as it moves through time, and in order to define appropriate strategies. It is also a requirement that functional aspects, studied separately in other units, are drawn together to evaluate how they should contribute to the overall purposes and aims of an organisation as a whole. Finally, it is also

expected that knowledge of theoretical models will be supplemented by case study evaluation in student work-groups. Mintzberg (1989) reported that success in policy and strategy level processes such as these depend on management thinking that is more relational, holistic and intuitive than ordered, sequential and analytical. This sort of work is deemed to be consonant with the scenario defined under category (a) above. It is therefore hypothesised that (***Hypothesis 3***) *the more intuitive a student's cognitive style, the higher will be his or her Business Policy and Strategy unit grade.*

Finally, another unit of study requires students to develop an understanding of individual stages and inputs to marketing planning by developing skills in analysing practical marketing problems and formulating appropriate marketing strategies to deal with them. The unit encourages and facilitates the application of the theories, concepts and techniques of marketing management, and publishes learning outcomes from which the students must demonstrate management of the overall planning, implementation and control processes of marketing. Students are expected to apply techniques and models to the marketing planning process, to undertake comprehensive analysis of markets, customers and competitors, to develop a marketing plan, and to communicate analyses effectively using both written and verbal formats. Mintzberg (1989) reported that planners of this kind are expected to proceed in their work through a series of logical, ordered steps, each one involving explicit analysis. This work is therefore deemed to be consonant with the scenario defined under category (b) above. Hence, it is hypothesised that (***Hypothesis 4***) *the more analytic a student's cognitive style, the higher will be his or her Marketing Planning unit grade.*

METHOD

Sample

The sampling frame was comprised of 731 students studying for their final year of a B.A. degree in Business Administration at a University in the North of England between 1995 and

1998. Four hundred and twelve students returned questionnaires, which represents an overall response rate of 56 per-cent. Two hundred and three of the student responses were from women, representing 49 per-cent of the overall sample.

Measures

Cognitive Style

The Cognitive Style Index (CSI) (Allinson & Hayes, 1996), a self-report questionnaire designed to assess the superordinate dimension of cognitive style described above was administered to all students in order to assess the generic, intuitive-analytic dimension of cognitive style. Each of the 38 items has a true-uncertain-false response mode, and scores of 2, 1 or 0 are assigned to each response, the direction of scoring depending upon the polarity of the item. The nearer the total score to the theoretical minimum of zero, the more intuitive the respondent and the nearer to the theoretical maximum of 76, the more analytical the respondent. Reliability of the CSI is good with test-retest correlations ranging from 0.78 to 0.90 (Allinson & Hayes, 1996; Armstrong, 1999; Murphy *et al*, 1998) for subjects re-tested after intervals of up to 8 weeks, and Cronbach alpha coefficients ranging from 0.86 to 0.92 (Armstrong, 1999; Allinson & Hayes, 1996; Murphy *et al*, 1998) for various managerial, professional and student groups. Construct validity is indicated by items loading on to a single factor in most previous studies, and significant correlations with, for example, scores on the Myers-Briggs Type Indicator (Myers, 1962), various personality dimensions and job level (Allinson & Hayes, 1996).

Ability

Overall academic achievement was determined by collecting data from the University records system for final, overall degree grades of individual students. A 16-point scale where zero indicates catastrophic failure and sixteen indicates maximum possible academic achievement

is used to represent this. This was deemed to be an accurate representation of a student's overall ability due to the fact that this final grade represents an aggregation of scores from a wide range and variety of business studies subjects.

Ability on tasks believed to be consonant with the scenarios suited to particular cognitive styles discussed above was determined by extracting grade points from the University records system for the Business Policy and Strategy Unit, Marketing Planning Unit, and Research Dissertation Unit. These grades were represented on the same 16-point scale described above.

ANALYSIS AND RESULTS

Table I shows statistical analyses using independent samples t-tests that revealed there were no significant differences between grades achieved by males and females for any of the units studied. Subsequent analyses into the effects of cognitive style on performance were therefore considered to be gender neutral. However, it was revealed that female management students were more analytic ($M = 44.32$, $SD = 11.72$, $n = 203$) than male management students ($M = 41.23$, $SD = 11.66$, $n = 218$). The difference was significant ($t = 2.71$, $p < .01$).

Table I about here.

In order to test the effects of cognitive style on performance, the student sample was divided into two groups on the basis of their cognitive styles. CSI scores were designated low (intuitive) or high (analytic) according to whether they were \leq or $>$ 43. These thresholds were chosen to ensure two groups of approximately equal size. Table II shows descriptive statistics and the results of a series of independent samples t-tests for the two groups of intuitive and analytic individuals.

Table II about here.

A potential problem with dichotomising data in the manner described is that if one student has a cognitive style index of 43, and another has an index of 44, they are considered to be different (i.e. intuitive and analytic respectively). The sample of students was therefore divided into three groups on the basis of their cognitive styles in order to extend the data analyses. CSI scores were designated low (intuitive), medium (integrated) or high (analytic) according to whether they were ≤ 38 , between 39 & 48, or ≥ 49 . These thresholds correspond to the 33rd and 66th percentile scores of the sample. Table III shows descriptive statistics and the results of a series of one-way analyses of variance tests for the three groups of individuals. Support for this approach can be found in the work of Agor (1984), who discusses three broad types of management style for making decisions. He talks of the left brain types stressing the employment of analytical and quantitative techniques. In the complementary style using right brain skills, he suggests that reliance is placed on feelings before facts when making decisions, where problems are solved by looking at the whole often with inadequate information or data at hand. A third style, he suggests, would be called integrated, employing both left and right brain skills interchangeably as the situation demands.

Table III about here.

These results will now be considered in four sections as defined by research hypotheses 1, 2, 3, & 4.

Cognitive Style and Overall Degree Performance (Hypothesis 1)

An independent samples “t” test revealed that analytic students from the academic sample achieved higher overall degree grades ($M = 10.20$, $SD = 1.66$, $n = 190$) than intuitive students ($M = 9.77$, $SD = 1.65$, $n = 176$). The difference was significant ($t = -2.47$, $p = .014$). A

correlational analysis for the whole academic sample also revealed a statistically significant, though weak relationship between students' cognitive styles and degree grade ($r = +.110$, $n = 336$, $p < .05$, two tails).

The analyses of variance reported in Table III also show that analytic students achieve significantly higher overall degree grades than do intuitive students. Students falling into the integrative category, however, achieve grades between these two groupings though the differences are not significant.

Hypothesis 1 is therefore rejected.

Cognitive Style and Performance in the Business Policy and Strategy Unit (Hypothesis 2)

An independent samples "t" test on the academic sample revealed that there was no significant difference ($t = -1.12$, $p > .05$) between grades awarded for analytic students ($M = 9.59$, $SD = 2.19$, $n = 190$) and intuitive students ($M = 9.33$, $SD = 2.17$, $n = 174$) studying the Business Policy and Strategy unit.

However, the analyses of variance reported in Table III show that analytic students achieve significantly higher grades for this unit than do students falling into either the intuitive or the integrative groupings which directly opposes the research hypothesis.

Hypothesis 2 is therefore rejected.

Cognitive Style and Performance in the Marketing Planning Unit (Hypothesis 3)

An independent samples "t" test revealed that analytic students from the academic sample achieved higher grades ($M = 10.28$, $SD = 1.92$, $n = 106$) than intuitive students ($M = 9.56$, $SD = 2.07$, $n = 88$) studying the Marketing Planning unit. The difference was significant ($t =$

-2.52, $p < .01$). A correlation analysis revealed a statistically significant relationship between students' cognitive styles and grades awarded ($r = +.205$, $p < .01$, two tails, $n = 194$).

As was the case with overall degree grades, the analyses of variance reported in Table III also show that analytic students achieve significantly higher overall degree grades than do intuitive students. Once again, students falling into the integrative category achieve grades between these two groupings but the differences are not significant.

Hypothesis 3 is therefore accepted.

Cognitive Style and Performance in the Research Dissertation Unit (Hypothesis 4)

An independent samples "t" test revealed that analytic students from the academic sample achieved higher grades for their final year research projects ($M = 10.30$, $SD = 3.07$, $n = 209$) than intuitive students ($M = 9.70$, $SD = 2.89$, $n = 192$). The difference was again significant ($t = -2.05$, $p < .05$).

However, the analyses of variance reported in Table III reveal no significant differences between the analytic, integrative or intuitive student groupings. Support for Hypothesis 4 is therefore mixed.

DISCUSSION AND CONCLUSIONS

The primary purpose of the present study was to determine whether cognitive style was an important factor influencing performance on tasks the categories of which were deemed to be consonant with individuals' styles of working. In two of the three criteria examined, statistically significant results were obtained that linked cognitive style to performance. As hypothesised, individuals whose dominant cognitive styles were analytic performed significantly better than those whose cognitive styles were wholist/intuitive when performing

tasks requiring detailed and comprehensive data collection, evaluation and analysis in order to carefully develop a marketing plan. Once again, as hypothesised, students who engaged in the solitary task of producing an 8000-word research dissertation requiring detailed and systematic collection and analysis of data, and who were expected to demonstrate logical and linear progression through careful planning and scheduling over an eight month period, performed significantly better when their dominant cognitive styles were analytic.

However, there was no support for the hypothesis that wholist/intuitive individuals would perform better on tasks relating to business policy and strategy formulation, believed by some (e.g. Mintzberg, 1989) to be better suited to individuals sharing this dominant mode of cognitive style. Indeed, it was rather surprising to find that when the sample was tri-chotomised into intuitive, integrative and analytic cognitive style groupings, analytic individuals also performed better than the other two groups in this unit of study.

A secondary aim of the study was to test the hypothesis that cognitive style is unrelated to overall ability for students of Business and Management Studies. Again, a rather surprising result revealed that individuals whose dominant cognitive styles were analytic significantly out-performed those whose cognitive styles were wholist/intuitive.

From earlier discussions in this paper, it is clear that cognitive style, in itself, is unlikely to be related to intelligence. Kirton (1978) and Riding & Pearson (1994) presented empirical evidence of this when they reported an orthogonal relationship between cognitive style and intellectual ability. Direct relationships which have been reported in the literature are likely to be due either to the use of cognitive style instruments which overlap style with spatial ability and therefore intelligence, or to inappropriate methods of assessing intelligence/ability which may favour one cognitive style over the other. With respect to the former, a cognitive style instrument was chosen for the present research that did not depend on spatial ability. With respect to the problem of using inappropriate measures of ability, this study has

attempted to overcome this by deliberately choosing performance indicators which stem from subject areas believed to be consonant with (e.g. policy & strategy, planning, research) or in dissonance with (e.g. overall degree grades) particular cognitive styles. So why should students with analytic cognitive styles perform significantly better in the Policy and Strategy Unit and on overall ability defined by final degree grades? One variable that was not properly controlled was the method of assessment applied to these various units of study. This would have been difficult due to the fact that assessment methods were rigidly defined in course documentation, validated through formal university policies and procedures. The question of whether these assessment methods had an effect on the reported results, however, requires further consideration.

If one considers that the overall results appear to have demonstrated that analytic individuals are favoured over intuitive individuals in terms of their ability to achieve higher performance grades in the field of Business and Management Studies, it may be argued that this leads to a potentially serious dilemma. This dilemma arises from the fact that organisations have a strong tendency in their graduate recruitment process to favour those with higher degree classifications. According to the findings of this study, this also reflects the degree to which these individuals are analytic rather than intuitive. But some authors (e.g. Mintzberg, 1989; Taggart et al, 1985; Simon, 1987) have argued that intuition is favoured over analysis where key managerial processes are involved. For example, Mintzberg (1989, p49) reports that:

“The key managerial processes are enormously complex and mysterious (to me as a researcher, as well as to the managers who carry them out), drawing on the vaguest of information and using the least articulated of mental processes. These processes seem to be more relational and holistic than ordered and sequential, more intuitive

than intellectual; they seem, in other words, to be most characteristic of right-brain activity’.

This raises the important question of whether or not academic institutions are assessing the appropriate skills. If potential employers of Business and Management students are seeking to recruit graduates who possess, metaphorically speaking, these right brain skills, then existing methods of assessing the ability of Business and Management students might reasonably be questioned. Referring to the methods of assessment and marking criteria for the units of study considered in the present research (Table IV), it can be seen that there is a strong likelihood of there being an orientation bias favouring individuals whose dominant cognitive styles are analytic. These assessment methods, typical of many Business Schools, are predominantly reliant on written assignment formats where assessment criteria are based on the expectation of systematic analysis and evaluation of information resulting in cogent, structured, and logically-flowing arguments. Although analytic students, who tend to prefer structured situations that are impersonal in nature, may prefer such methods, they are unlikely to be suited to intuitive students who tend to have a predominantly social orientation, favouring interpersonal situations that allow interaction (e.g. Armstrong, 1999a; Armstrong, 1999b; Allinson, Armstrong, & Hayes, (under review). Many alternative and innovative forms of assessment are available which would appeal to this type of student, such as poster sessions, video production, debating, role play, group-work with oral presentations, and so on. If assessment methods cannot be devised which are totally independent of orientation bias, perhaps they can at least ensure that equal amounts of analysis and intuition are assessed during the learning process (a whole brain approach).

Table IV about here.

Whilst selecting instructional techniques most appropriate to the cognitive styles of learners has often been considered to be a positive step in optimising learning processes, matching the type of assessment with the cognitive needs of students has seldom been attempted. This is an important area for future research because if the actual assessment of ability is biased in favour of those able to use their analytical skills more effectively, then employment selection criteria based, for example, on degree classifications may favour the wrong type of candidate in some circumstances.

Table I. Gender, Performance and Descriptive Statistics for the Cognitive Style Index

Cognitive Style / Unit of study	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>Range</i>	<i>df</i>	<i>t</i>
Cognitive Style (whole group):	421	42.72	11.78	5 - 73	419	2.71**
<i>Male group</i>	218	41.23	11.66	5 - 73		
<i>Female group</i>	203	44.32	11.72	9 - 70		
Overall Degree (whole group):	366	10.00	1.66	2.4 – 13.8	364	1.24
<i>Male group</i>	183	9.89	1.73	2.4 - 13.8		
<i>Female group</i>	183	10.11	1.59	4.2 - 13.6		
Business Policy and Strategy Unit (whole group):	364	9.47	2.18	3.0 – 15.0	362	0.63
<i>Male group</i>	182	9.40	2.12	3.0 – 15.0		
<i>Female group</i>	182	9.54	2.23	3.0 – 15.0		
Marketing Planning Unit (whole group):	194	9.95	2.02	3.0 – 15.0	192	-1.20
<i>Male</i>	103	10.12	2.00	4.0 – 15.0		
<i>Female</i>	91	9.77	2.03	3.0 – 14.0		
Research Dissertation Unit (whole group):	401	10.01	3.00	0.0 – 16.0	399	-0.17
<i>Male</i>	207	10.03	2.94	1.0 – 16.0		
<i>Female</i>	194	9.98	3.07	0.0 – 16.0		

** $p < 0.01$ (2-tailed)

Table II. Influence of Cognitive Style on Performance of Analytic and Intuitive Groupings

Unit of study	Intuitive Individuals			Analytic Individuals			<i>df</i>	<i>t</i>	<i>Sig.</i> (2-tailed)
	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>n</i>	<i>Mean</i>	<i>SD</i>			
Overall Degree Grade	176	9.77	1.65	190	10.20	1.66	364	-2.47*	.014
Business Policy and Strategy	174	9.33	2.17	190	9.59	2.19	362	-1.12	.262
Marketing Planning	88	9.56	2.07	106	10.28	1.92	192	-2.52**	.013
Research Dissertation	192	9.70	2.89	209	10.30	3.07	399	+2.05*	.041

* $p < 0.05$ (2-tailed), ** $p < 0.01$ (1-tailed)

Table III. One-way Analyses of Variance for Analytic, Integrated and Intuitive Groupings

<u>Unit of study</u>	1			2			3			<i>df</i>	<i>F</i>
	<u>Intuitive Types</u>			<u>Integrated Types</u>			<u>Analytic Types</u>				
	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>n</i>	<i>Mean</i>	<i>SD</i>		
Overall Degree Grade	113	9.74 ₃	1.82	122	10.03	1.41	131	10.20 ₁	1.73	2,363	2.32*
Business Policy and Strategy	112	9.33 ₃	2.35	121	9.15 ₃	2.30	131	9.88 _{1,2}	1.83	2,361	3.91**
Marketing Planning	57	9.40 ₃	2.23	64	10.06	1.73	73	10.29 ₁	2.02	2,191	3.29**
Research Dissertation	123	9.78	2.96	133	10.06	2.93	145	10.15	3.10	2,398	0.54

* $p < 0.1$, ** $p < 0.05$

Subscript to a mean refers to a group whose mean is significantly different (Duncan multiple range test).

Table IV. Methods and Criteria of Assessment

Unit of Study	Method of Assessment	Marking Criteria
Business Policy and Strategy Unit	50% weighting: Individually written assignment of 2000 words which must be structured (e.g. abstract, introduction, methodology, results, conclusions).	<i>Content</i> – quality of research and analysis undertaken and the use of initiative in finding sources of information. <i>Report</i> – quality and clarity of writing and ability to demonstrate command over the subject area.
	50% weighting: Individual examination based on a case study	None published.
Marketing Planning Unit	40% weighting: groupwork and oral presentation.	Illustration of knowledge and understanding by providing a clear logical line of argument. Example of grades awarded – A (best) - thorough analysis and intelligent, confident group presentation. D – minimal fluency of arguments and logic sparse.
	60% weighting: Individually written piece of work based on case study.	Demonstration of analytical skills, communication skills, and problem solving skills.
Research Dissertation Unit	Project planning skills. Submission of an 8000 word research dissertation. Oral examination.	10% - ability to plan, monitor and control a working schedule. 40% - quality of research and analysis undertaken. 40% - quality, clarity and structure of the final written report. 10% - ability to verbally communicate his/her conduct of the project and command over its subject area.
Overall degree Grade	Various.	Various.
