Listening to Sad Music in Adverse Situations: How Music Selection Strategies Relate to
Self-Regulatory Goals, Listening Effects, and Mood Enhancement

Final draft

Annemieke van den Tol
and
Jane Edwards

Abstract

Adults' ($N=220$) reported motivations for listening to sad music after experiencing adverse negative circumstances were examined by exploring how their music selection strategies related to (a) their self-regulatory goals, and (b) reported effects of listening. The effects of music selection strategies, self-regulatory goals, and reported effects on the achievement of mood enhancement were also explored using a retrospective survey design. The findings indicate that music choice is linked to the individual's identified self-regulatory goals for music listening and to expected effects. Additionally, the results show that if individuals had intended to achieve mood enhancement through music listening, this was often only reported to be achieved by first experiencing cognitive reappraisal or distraction. The selection of music with perceived high aesthetic value was the only music selection strategy that directly predicted mood enhancement. Where respondents indicated that they chose music with the intention of triggering memories this was negatively related to the self-regulatory goal of mood enhancement.

Keywords: Mood Enhancement, Music Listening, Negative Affect, Sadness, Sad Music, Self-regulation, Selection Strategies

Listening to Sad Music in Adverse Situations: How Music Selection Strategies, Relate to Self-Regulatory Goals, Listening Effects, and Mood Enhancement

The effects of and self-regulatory goals for music listening are of interest to scholars in psychology, musicology and sociology, and for practitioners in music therapy and music education (Edwards, 2011; Hallam, Cross, & Thaut, 2011). Music listening effects have traditionally been examined through laboratory tests of responses to experimenter-selected music. However, recent research has started to focus on individuals' reports of the effects of self-selected music, in order to further understand aspects of everyday music use (Rentfrow, 2012).

The current study investigated music listening in order to understand people's self-regulatory goals, music selection strategies, and the effects of self-selected music that the listener identified as sounding *sad*; what we describe as *Self-Identified Sad Music* (SISM). We are interested in why people sometimes decide to listen to music that they identify as sad when they are already feeling sad after experiencing an adverse event. We believe that we can learn about people's motivation for listening to sad music by asking people to reflect upon their experiences and describe their choices.

Motivations to Listen to Sad Music When Feeling Sad

Several recent studies provide evidence that people listen to sad music when experiencing sadness or adverse negative affective states (Hunter, Schellenberg, & Griffith, 2011; Matsumoto, 2002; Saarikallio & Erkkilä, 2007; Schellenberg, Peretz, & Vieillard, 2008; Van den Tol, 2012, 2013). For instance, results of a focus group

LISTENING TO SAD MUSIC

study that was conducted with 11 Finnish adolescents showed that participants who were sad or angry were inclined to listen to SISM in order to think through and work out problems, as a distraction from problems, for expressing emotions, and to attain closure (Saarikallio & Erkkilä, 2007). Similarly, Miranda and Claes (2009, P. 218) indicated that “music listening can be thought of as being used intentionally by adolescents for coping with daily stressors.” Moreover, experimental research shows that the desire to listen to sad music is strongest directly after participants have been experiencing a negative mood, whereas people are more likely to listen to uplifting music when some time has passed after negative mood induction (Chen, Zhou, & Bryant, 2007).

Music Listening and Self-Regulation

A range of recent studies have investigated the extent to which self-regulatory goals can be attained through music listening. For example, music listening can be used to change, maintain, or reinforce affect, moods and emotions (i.e. Chen, Zhou, & Bryant, 2007; Knobloch & Zillmann, 2002; Lonsdale & North, 2011), for relaxation (Thayer, Newman, & McClain, 1994), for reminiscence or to trigger nostalgia (i.e. Knobloch & Zillmann, 2002; Van Goethem & Sloboda, 2011), for stimulating cognitive effects (Sloboda, Lamont, & Greasley, 2009), for meaning enhancement (Maher, Van Tilburg, & Van den Tol, 2013), or as a platform for mental work or cognitive reappraisal (i.e. Saarikallio, 2007, 2008; Saarikallio & Erkkilä, 2007; Lonsdale & North, 2011).

Consistent with the above findings, listening to SISM when feeling sad has also been found to serve many self-regulatory functions. In a recent study, 65 adults were asked to write about a recent occasion in which they had decided to listen to SISM when they were feeling sad (Van den Tol & Edwards, 2011). Participants

LISTENING TO SAD MUSIC

indicated that listening to SISM could have a variety of psychological effects: (*Re-experiencing Affect*, which means getting in touch with or intensifying affective states, *Retrieving Memories*, which means retrieving episodic memories associated with the music, *Cognitive*, which refers to the use of music for cognitive reappraisal, *Friend*, where the music was described as serving as a symbolic friend, *Social*, reflecting feeling closer to or emotionally connected to (real) friends and family, *Distraction*, which refers to the use of music for distraction and keeping the mind of from unwanted feelings and thoughts, and *Mood enhancement*, which involves making one feel better or less sad. Most participants indicated that listening to sad music when feeling sad could sometimes be used as an effective way to cope with an adverse event.

Listening to Sad Music When Feeling Sad and Music Listening Strategies

Results of a number of recent studies suggest that people use different strategies to select music, and that the selection of these strategies depends on the goals they are pursuing in a specific situation (Chen, Zhou, & Bryant, 2007, DeNora, 1999, Lonsdale & North, 2011; Saarikallio & Erkkilä, 2007; Thoma, et al., 2012). The following music selection strategies were found in a qualitative study about listening to SISM when feeling sad (Van den Tol & Edwards, 2011): *Connection*, meaning selecting a specific piece of music because the music portrays affect or has lyrics that the listener can identify with at that moment, *Memory Triggers*, referring to the selection of music because the music has associations with past events and persons, *High Aesthetic Value*, which involves selecting the music because one perceives the music to be ‘good’ or ‘beautiful music’, and also *Message Music*, where music is chosen that conveys a message to which the listener wants to relate. Moreover, the music selection strategies and self-regulatory effects were linked to each other.

LISTENING TO SAD MUSIC

Specifically people often seemed to: use a *connection* selection strategy when they wanted to (*re-*) *experiencing affect*, people often aimed for *cognitive reappraisals* when they used music which conveys a *message*, when people selected music with a *high aesthetic value* they often aimed for *distraction* or *mood enhancement*, when people used a *memory triggers* selection strategy they often did so in order to *retrieve memories*, to feel *social* and to (*re-*)*experiencing affect*. It was indicated, however, that quantitative follow up research with a larger sample is needed, in order to generalize these findings to a larger population (Creswell, Plano Clark, Guttman, & Hanson, 2003).

Listening to Sad Music when Feeling Sad and Mood Enhancement

Some of the participants in the study by Van den Tol and Edwards (2011) indicated they experienced mood enhancement as a result of listening to SISM when feeling sad. Many different psychological processes have been suggested to play a role in positive affective experiences that can be experienced as a result of listening to sad music (Blood & Zatorre, 2001; Huron, 2011; Kallinen & Ravaja, 2006; Matsumoto, 2002; Saarikallio, 2008; Vuoskoski, Thompson, McIllwain, & Eerola, 2012). Listening to self-identified pleasant music result in brain activity in regions associated with reward and displeasure inhibition (Blood & Zatorre, 2001; Menon & Levitin, 2005; Schubert, 1996). Moreover, findings by Vuoskoski, Thompson, McIllwain & Eerola (2012) indicate that people who score high on the traits *aesthetic appreciation* and *empathetic engagement* enjoy sad music to a greater extent than people who score low on either one of these traits. Based on the above findings it is likely that we will also find indications that mood enhancement can be achieved directly as a result of selecting sad music that is judged to have high aesthetic value. More specifically, it may be likely that people will consciously select music with high

LISTENING TO SAD MUSIC

aesthetic value when they aim to achieve mood enhancement after having experienced an adverse event.

A variety of different studies indicate that engagement in cognitive re-appraisal and behavioural diversion (e.g. listening to music to distract the self of problems) or distraction are among the most effective behavioural strategies used to pursue mood enhancement (Hayes, et al., 2010, Kross, Ayduk, & Mischel, 2005; Totterdell & Parkinson, 1999). In line with this, it has been found that the common use of music for diversion (a concept that relates to listening to music for distraction) and mental work (a concept that includes listening to music for cognitive reappraisal) related positively to perceiving oneself to be efficient in repairing ones mood (Saarikallio, 2008). This was found in a cross-sectional survey that was conducted among a group of Finnish adolescents. It is hence likely that listening to SISM may also result in mood enhancement when music is used for cognitive re-appraisal or distraction, and that people use these effects of music when they aim to achieve mood enhancement.

Listening to SISM when feeling sad has been found to be used to experience acceptance, support, or empathy from the music, which has been described as experiencing that the music is a *friend* (Van den Tol & Edwards, 2011). Findings from a study on the use of music conducted among adolescents (Saarikallio, 2008) indicated that the common use of music for solace (a concept that includes listening to music to experience friendship with the music) was positively correlated with mood-repair. However, exploration of earlier collected narrative data about SISM when feeling sad (Van den Tol and Edwards, 2011) did not reveal any examples in which participants experienced mood enhancement as a result of ‘the experienced friendship with the music’. We hence believe that the friendship element in sad music may

LISTENING TO SAD MUSIC

potentially represent a different value than the *solace* element in music in general. In other words, the current research is hoped to shed more light on how the imagined friendship that is experienced during SISM can be categorized in terms of perceived coping value.

In previous research on SISM it was found that the memories that are recalled during listening to SISM often involve missed loved ones, and foregone times (Van den Tol & Edwards, 2011). This description of memories seems to resemble some elements of nostalgia. Wildschut, Sedikides, Arndt, & Routledge (2006) described nostalgia as a bittersweet emotion that is a happiness-related experience but also contains elements of negative emotionality. They also indicated that nostalgia often involves the self as a protagonist in interactions with close others. Interestingly, research has indicated that people often engage in nostalgia in order to repair negative moods (Wildschut, et al., 2006). Moreover, Barrett, Grimm, Robins, Wildschut and Sedikides (2010) found that sad moods can motivate people to listen to music as a means to retrieve nostalgic memories and enhance positive moods. However, findings of previous qualitative research on SISM indicated that only some people felt better after having retrieved memories during SISM, whereas others participants reported to find it unpleasant to engage in memory retrieval during music listening. Moreover, one participant indicated to have expected to feel better but to unexpectedly feel worse after having listening to the music of his choice. It is hoped that the current research provides more light on the phenomena of SISM memories retrieval and mood enhancement.

Aims

Three specific aims guided this research:

LISTENING TO SAD MUSIC

(1) As a first aim we sought to identify several distinct groups of music selection strategies, self-regulatory goals and self-reported effects. More specific we wanted to find out how the items on the SISM questionnaire that we designed would statistically group together.

(2) As a second aim we sought to ‘understand music selection strategies’. More specifically, we were interested in people’s motivations to select music with a specific music selection strategy. This part of the research explored the strengths of previously indicated effects of selecting music with a specific music selection strategy on specific self-regulatory goals and reported effects ¹

(3) As a third aim we sought to ‘understand mood enhancement’. More specific, we wanted to examine which music selection strategies, which self-reported effects, and which self-regulatory goals predicted the experience and achievement of mood enhancement.

Hypotheses

An overview of more specific predictions in relation to each of the above mentioned aims are provided below:

(1) It was predicted that categories of items would represent the goals, effects, and strategies that were observed in previous research on SISM when feeling sad.

(2a) Participants who use a connection selection strategy will be most likely to report to feel sadness and want to experience sadness as a self-regulatory goal.

(2b) Participants who use a memory trigger selection strategy will be most likely to report to experience memories, to feel closer to others, and to feel sadness, and to also have pursued these effects as a self-regulatory goal.

LISTENING TO SAD MUSIC

(2c) Participants who select music with a direction strategy will be most likely to report to experience cognitive reappraisals and to also have pursued this effect as a self-regulatory goal.

(2d) Participants who select music with a high aesthetic value selection will be most likely to report to experience distraction, or mood enhancement and to also have pursued this effect as a self-regulatory goal.

(3a) It was predicted that participants would report to have experienced mood enhancement when participants also reported to have experienced cognitive or distracting effects of listening to SISM, and that people actively pursue cognitive or distracting music listening experiences when they aim to experience mood enhancement. In other words, distraction and cognitions will mediate mood enhancement independent of which music selection strategy is used.

(3b) It was predicted that selecting the SISM (just) for its high aesthetic value will be the only music selection strategy that can predict mood enhancement as a goal or as an effect (independently of other self-regulatory goals, or other recalled effects).

Methods

Participants

220 Adults volunteered to participate in this study (135 females, 80 males, and 5 undisclosed). Participants' ages ranged from 18 to 69 ($M = 28.30$ $SD = 11.51$). This study represented participants of twenty-six different nationalities; 74 participants were Caucasians from the USA, 38 were Irish, 24 were Dutch, 12 were British, 10 were African-Americans from the USA, 9 were Australian, 8 were

LISTENING TO SAD MUSIC

Canadian, 6 were Greek, 3 were Malaysian, 3 were Belgian, 22 participants indicated having another nationality, and eleven participants did not report their nationality.

Measures

A questionnaire was developed for the purpose of investigating people's recalled music listening motivations and effects of SISM during a recent event when feeling sad. This questionnaire started with requesting the participant to think back to an adverse emotional event they had experienced after which they had listened to music that portrayed sadness. Participants were then asked to rate several statements, each on 5-point interval scales ranging from 1 (*I do not agree with this at all*) to 5 (*I very much agree with this*). To decrease error a 'not applicable' option was added to this interval scale. Participants firstly rated several statements relating to the music selection *strategies* they had used for selecting the music ("I chose to listen to the sad music because..." for example, "...the music contains lyrics that communicated hope."). Next, they rated several statements relating to self-regulatory *goals* they wanted to achieve as a result of listening to the sad music ("The reasons I listened to the sad music was..." for example, "... to bring back memories."). Participants then rated several statements relating to the recalled *effects* of listening ("Listening to this sad music did..." for example, "...bring back memories"). Participants' level of attention were checked by using two attention check items, that explicitly instructed participants how to rate them. These items were placed in the middle and at the end of the questionnaire. After rating all statements, participants provided information about age, nationality, and gender.

The self-report of experiences served a valuable purpose: We were interested in people's *everyday life* experiences of listening to SISM when feeling sad after adverse circumstances. This may not always be usefully studied within a laboratory or

LISTENING TO SAD MUSIC

controlled environment where emotional states have to be induced, and ethical issues may subsequently arise. Consistent with approaches such as those from within narrative research (Gabrielsson; 2011; Moen, 2006) we advocate the use of retrospective recall in human subject research as a means by which humans' construction of their experiences can be usefully examined. To quote (Gabrielsson, 2011, p. 455) "They are perhaps never completely faithful to the original, but can nevertheless be said to be accurate in the sense that they represent the meaning that the experience had to the person concerned". Rather than focusing on what might be flawed or inaccurate about the findings, we contend that as long as our findings are indicated to be based on recall rather than real time experiences our method is congruent with many current approaches in research about human experience.

Procedure

Participants were recruited by email invitations for which we used the University email system and by invitations via the internet, including social science research networks. The invitation stated that University researchers were looking for participants to volunteer for a study that explores people's motivations to listen to sad music when feeling sad. The invitation included a link to the website where a detailed information sheet, a consent form, and the study were provided. Upon completing the study participants were thanked for their participation and were provided with a comment box for any additional information that they wished to share.

A total of 10 participants who either failed to provide the correct answer to the attention checks, who missed more than 5 statements, or who had selected the 'not applicable' option more than 5 times, were dropped from the sample. A missing value analysis was conducted on the dataset to be able to also use the responses of participants from which only some data was missing (Tabachnick & Fidell, 2007).

LISTENING TO SAD MUSIC

The research procedure was approved by the Faculty of Arts, Humanities, and Social Science Research Ethics Committee of the University of Limerick, Ireland.

Results

Aim 1: Structure of the Data

Five Principal-Component analyses were conducted to investigate the structure of the data in order to statistically explore aim 1. Principal-Component analysis is a statistical approach used for investigating underlying structures of items and for grouping items together based on their magnitudes of covariance (e.g., Tabachnick & Fidell, 2007). In order to be able to use the extracted components for the investigation of some of the other research questions in which regression based techniques are used it was important to extract components with relatively low multicollinearity (Ezekiel & Fox, 1959, p. 283-284). Hence we employed a varimax rotated solution, deleted items that loaded higher than 0.45 on more than one component, and conducted new analyses with the remaining items until several distinct multiple-item components occurred (Hair, Anderson, Tatham, & Black, 1998; Tabachnick & Fidell, 2007).

A categorization of five distinct direct goals and five distinct direct effects was indicated (see Table 1 and 2). The direct goals and effects were labelled: *Sadness*, *Memories & Social*, *Distraction*, *Cognition* and *Friend* (reflecting the labels of Van den Tol and Edwards, 2011). *Sadness*, referred to getting in touch with or intensifying affective states, *Memories and Social*, whereas the memory part of this label referred to retrieving episodic memories associated with the music, and the social part of this label reflected feeling closer to or emotionally connected to (real) friends and family, *Cognitions*, referred to the use of music for cognitive reappraisal, *Friendship*, referred to that the music can serve as a symbolic (imaginary) friend, and *Distraction*, referred

LISTENING TO SAD MUSIC

to the use of music for distraction and keeping the mind of from unwanted feelings and thoughts.

PLEASE INSERT TABLE 1 AND 2 HERE

One component was found in both analysis on indirect goals and indirect effects. The items of this component (see Table 3 and 4) reflected the description of the category *Mood Enhancement*. The label *Mood Enhancement*, referred to making feel better or less sad.

PLEASE INSERT TABLE 3 AND 4 HERE

Three groups of items which represented distinct music selection strategies were found (see Table 5). These were named: *Connection & Memory Triggers*, *High Aesthetic Value*, and *Direction* (reflecting the labels of Van den Tol and Edwards, 2011, 2012). *Connection & Memory Triggers*, where, connection referred to selecting music because the music portrays affect or has lyrics that the listener can identify with at that moment, and memory triggers referred to the selection of music because the music has associations with past events and persons, *High Aesthetic Value*, referred to selecting the music because one perceives the music to be ‘good’ or ‘beautiful music’, and *Direction*, referred to selecting music that conveys a message to which the listener wants to relate.

PLEASE INSERT TABLE 5 HERE

Aim 2: Understanding Music Selection Strategies

Linear regression analyses were conducted to investigate how each music selection strategies predicted people to aim for a specific self-regulatory goals or reported effects. ¹ Throughout each of these analyses, one music selection strategies was entered as an independent variable and one reported effect or self-regulatory goal was entered as a dependent variable (see Table 6 and Table 7).

PLEASE INSERT TABLE 6 HERE

All but one music selection strategies significantly regressed upon each of the direct self-regulatory goals and self-regulatory effects. The only non-significant regression was observed between using a *high aesthetic value* music selection strategy and the self-regulatory goal *memories and social*.

In line with the hypothesis (2a) *Connection* regressed strongest upon *sadness*, (2b) the music selection strategy *memory triggers* regressed strongest upon the goal and effect *memories & social*, but also yielded a strong regression with *sadness*. In line with the hypothesis (2c) the strategy *direction* regressed strongest upon the effect *cognition*, this regression coefficient was smaller, however, for the goal *cognitions*. Selecting music with a *direction* selection strategy regressed strongest upon the goal of *memories and social*, and also upon the goal *friendship*. In line with the hypothesis (2d) it was found that selecting music with a *high aesthetic value* selection strategy yielded the strongest regression upon *mood enhancement* but also produced a strong regression coefficient for *distraction* (see Table 6 and 7).

Aim 3: Understanding Mood Enhancement

LISTENING TO SAD MUSIC

Multiple-mediation analysis is a statistical test that is commonly used to explore the effects of one independent and several parallel mediating variables on one dependent variable (Preacher & Hayes, 2004; 2008). Several parallel mediation analyses were conducted in order to investigate to what extent *mood enhancement* was a direct or an indirect goal or effect of music listening. We investigated this for each different music selection strategy. More specific, we wanted to know to what extent each music selection strategy has an unique effect on experiencing mood enhancement, and to what extent direct effects/direct goals may have an unique effect in mediating these effects on mood enhancement. Each of these analyses were conducted with *one of the music selection strategies* as an independent variable, with all the *direct goals* or all the *direct effects* as parallel mediating variables, and with either *mood enhancement as a goal* or *mood enhancement as an effect* as a dependent variable (see Figure 1 for a graphic example of one these models, and table 8 and 9 for the results of these analyses).

In line with the hypothesis (3a) it was observed that the components *cognitions* and *distraction* played a significant mediating role in the relationship between music selection strategies and *mood enhancement*, for the analysis of each strategy and both for goals and for effects.

In line with the hypothesis (3b) the relationships between *mood enhancement* and music with *high aesthetic value* remained significant after controlling for the effect of the mediating variables. These results were found for both the analyses on self-regulatory goals and on reported effects. Moreover, none of the other significant regressions effects of music selection strategies upon mood enhancement remained significant after controlling for all other self-regulatory goals or for all other reported effects.

LISTENING TO SAD MUSIC

There were few other self-regulatory goals or reported effects that mediated mood-enhancement. However, an additional mediating relationship was observed for the selection of music with the goal *memories and social* on having the goal of *mood enhancement* when the mediating roles of direct goals were examined for selection of music with a *memory triggers* selection strategy. Moreover, when mediating effects of goals were taken into account for the selection of music with a *memory triggers* selection strategy the relationship between this music selection strategy and the goal of mood enhancement were reversed, which was a finding that was also not anticipated.

Discussion

The current research was guided by several hypothesis, most of which were confirmed by the analyses. In the paragraphs below an overview will be provided of the findings for each research question, and the implications of these findings.

Aim 1: Structure of the Data

The prediction regarding the structure of the data was that a distinction of strategies, goals, and effects would be observed relatively similarly to previous findings on listening to SISM when feeling sad (Van den Tol & Edwards, 2011). The current results largely confirmed this prediction. In the analysis on music selection strategies three components were observed, these components were named; *connection & memory triggers*, *high aesthetic value*, and *direction*. Please note that the label for the earlier proposed category *message music* has been replaced by the label *direction*. The items belonging to the earlier identified music selection strategies *connection* and *memory triggers* (Van den Tol & Edwards, 2011) loaded high on one component. It is important to note, however, that even though these strategies show

LISTENING TO SAD MUSIC

statistical overlap, findings (see Table 6) do suggest that distinct psychological processes guide these selection strategies. This statistical overlap may be explained by people's simultaneous use of these two music selection strategies.

In the analyses on indirect self-regulatory goals and effects one component was observed. This was in line with the expectations. This component represented *mood enhancement* and was labelled accordingly.

In the principal components analyses that were conducted on the direct self-regulatory goals and effects five components were observed. These components represented: *sadness, memories & social, cognitions, friendship, and distraction*. Please note that these labels represent all earlier proposed *self-regulatory function* categories (Van den Tol & Edwards, 2011) but that some of the labels have been slightly changed in order to make the names of the labels more consistent with each other. Items that represented the earlier proposed distinct categories of *retrieving memories* and *social* (Van den Tol & Edwards, 2011) represented only one component; *memories & social*. This is in line with observations that the memories that are retrieved through music listening are often of a social nature (Van Goethem & Sloboda, 2011).

Aim 2: Understanding Music Selection Strategies

Almost all the music selection strategies yielded positive significant relationships to each of the goals and effects. These findings may either indicate that people pursue more than one goal when they select music (providing this overlap in regressions) or that each music selection strategies can be used to achieve more than one specific goal. In line with literature (Saarikallio & Erkkilä, 2007; Van Goethem & Sloboda, 2011) we believe that it is most likely that both these theories are correct.

LISTENING TO SAD MUSIC

The specific relationships that did not yield significance were between selecting music with *high aesthetic value* and the goal and effect of *memories & social*, indicating that it is not likely that people use this music selection strategy in order to achieve this goal or experience this effect.

The following findings were observed with regards to the strongest regression coefficients for each music selection strategy with each goal or effect: Selected music with a *connection* selection strategy yielded the strongest results for aiming to use music for *sadness* and reporting to have experienced *sadness* as a result of listening to the music. This was in line with the hypothesis (2) and may be explained as conscious self-regulatory use of music that portrays a certain emotion in order to experience emotional contagion (Juslin & Västfjäll, 2008; Knobloch & Zillmann, 2002). In line with the hypothesis (2b) the *memory triggers* selection strategy yielded a strong regression upon using music to experience *memories & social* and *sadness* and to experiencing *memories & social* and *sadness* as a reported effect of music listening. In line with these findings, it has been noted that music with memory triggers can be used effectively to retrieve memories and to be in touch with emotions (Baumgartner, 1992; Juslin & Västfjäll, 2008). As predicted (2c) people most often selected music with a *high aesthetic value* selection strategy when they aimed for *distraction*. We argue that the more beautiful music is, the easier it is for the listener to concentrate on the music. Moreover, these findings are in line with findings that stimulus that is perceived to have *high aesthetic value* will generate sensory pleasure and inhibit displeasure (Hekkert, 2006; Menon & Levitin, 2005). The strategy *direction* yielded a strong relation with experiencing *cognitions* as an effect of music listening, but not with having *cognitions* as a goal. Surprisingly it was found that people would rather select music with a *direction* selection strategy in order to pursue the experience the

LISTENING TO SAD MUSIC

effects *memories & social or friendship*. This was not entirely in line with the hypothesis (2d) and more research will be needed to further explore why this happened.

Aim 3: Understanding Mood enhancement

Several studies reported that listening to sad music can induce positive moods (Garrido & Schubert, 2010, 2011a, 2011b; Schubert, 2007; Kallinen & Ravaja, 2006; Vuoskoski, et al., 2012). Extending these findings we proposed and found that people select music with a (3b) *high aesthetic value* and engage in (3a) *distraction* and (3a) *cognitive reappraisal* in order to achieve mood enhancement. In line with these findings the use of *high aesthetic value* selection strategy and the engagement in *distraction* or *cognitive reappraisal* were also found to be effective self-regulatory strategies for achieving *mood enhancement* as a result of listening to SISM when feeling sad.

These findings resonate with findings from other music listening literature but also add insights to existing theory and findings. For example, Chen, Zhou, & Bryant, (2007) found that *during* negative moods people most strongly prefer to listen music with a negative valence, whereas people are more inclined to repair their mood by listening to more uplifting music *shortly after* a negative mood. They suggested that listening to sad music provides the opportunity to sort out one's feelings, and that this may explain why some people listen to sad music during sadness. Results of the current research indeed indicates that those people who had recalled to listen to SISM to sort out their feeling and thoughts during listening to sad music also felt more positive. Moreover, mood enhancement was additionally reported more often by participants who sought to provide opportunities for distraction and had selected the music for its aesthetic value.

LISTENING TO SAD MUSIC

It has to be pointed out that even though listening to SISM for *distraction* may very likely provide some listeners with mood enhancement, continuous use of music for distraction from negative moods may be an indicator of avoidant coping (Miranda & Claes, 2009; Garrido, & Schubert, 2011) or may even indicate problems with psychological adjustment (Hutchinson, Baldwin, & Oh, 2006).

As part of the parallel mediation analyses a reversed effect was observed between selecting music with a *memory trigger* selection strategy and having *mood enhancement* as a goal. This was found when the mediating roles of other goals were taken into account. Interestingly, people's expectations were not verified in the effects that they reported. We believe that these findings indicate that it is unlikely that many people recalled selecting SISM with a *memory trigger* selection strategy in order to try to achieve *mood enhancement* when they did not also pursue any of the other goals (distraction or cognitions) by which *mood enhancement* can be achieved. Zillmann (2000) argued that people sometimes engage in behaviour that may not have immediate rewards in terms of feeling, but is expected to have positive mood rewards in the long term. In terms of the current findings this may mean that some people find it more important to spend time retrieving memories than to enhance their mood, and that these people have expectations that this behaviour is rewarding in the long term.

In line with the abovementioned findings, we also did not observe that the reported effects or goal *memories and social connection* mediated the achievement or experience of *mood enhancement*. Although we did not examine nostalgic experiences in particular, these findings are nonetheless intriguing as research on nostalgia and music listening (Barrett et al., 2010) suggests an enhancing role of nostalgia. It is likely that differences in the designs of both studies have influenced the differences in results. For example, the current research focussed on *SISM* and the

LISTENING TO SAD MUSIC

research by Barrett et al., (2010) focussed on the effects of *music listening in general*. This may mean that people may be more likely to select *happy music* in order to retrieve nostalgic memories for mood-repair, and select sad music when they aim to be in touch with sadness as a mean to work out their feelings (delayed gratification). This argument is in line with the findings that people who score high on the trait nostalgia proneness are more likely to select happy music than people who are scoring lower on this trait (Batcho, 2007). It is however also possible that the differences between previous and current results occurred because we did not specifically measure nostalgia in the current research. As Batcho (2007) noted (p. 362): “one can remember without being nostalgic, but one can not be nostalgic without remembering.”

Not many participants reported to experience *mood enhancement* while simultaneously reporting to have felt sad, or had reported to simultaneously pursue both of these experiences. In other words, based on the current results it seems unlikely that *mood enhancement* occurs very often as a result of experiencing *sadness*, or that people try to first being in touch with or express affective experiences in the pursuit of *mood enhancement*.

Few participants reported to simultaneously have experienced mood-enhancement while also having experienced friendship. Based on this self-report it unlikely that many people experience *mood enhancement* when they experience *friendship* with the music, or that people are aiming to achieve *mood enhancement* when they aim to experiencing *friendship* with the music. These findings are different to findings of a study on music listening in general (Saarikallio, 2008) where it was found that a concept closely related to friendship (i.e. solace) related positively to mood enhancement. These differences in findings may potentially be explained by our

LISTENING TO SAD MUSIC

focus on SISM or sad affective state. Based on unpublished research, we suggest that friendship is pursued as a mean to experience delayed gratification as well as acceptance (Van den Tol & Edwards, under review).

Contributions

The current research provides several new insights into people's beliefs about the self-regulatory value of listening to SISM when feeling sad. Moreover, this research verified several previous findings on SISM when feeling sad by employing a large sample and adopting a converging method. The current research provided a self-regulatory perspective on the argument of how listening to sad music may contribute to a positive affective states (Blood & Zatorre, 2001; Huron, 2011; Kallinen & Ravaja, 2006; Matsumoto, 2002; Vuoskoski, et al., 2012). It is hoped that this self-regulatory perspective provides a broader perspective on mood-repair in relation to self-motivated music listening in *everyday life*. This is additionally the first study that statistically explores the self-regulatory value of a range of earlier identified music selection strategy used when deciding to listen to SISM when feeling sad. Hence providing further insights in what motivates people to select a specific piece of sad music when feeling sad.

Limitations and Future Directions

In terms of generalizability of findings it has to be noted that the current research was conducted using a retrospective survey design, meaning that findings represent people's recollection of having listened to SISM when feeling sad rather than people's experiences while engaging in this behaviour. Because this study focused on self-reported goals and effects we have to be careful with generalizing these findings to actual outcomes of music listening. Future research may seek to verify these findings with the use of Experience Sampling Methodology, which is a

LISTENING TO SAD MUSIC

method of research in which participants are asked to make notes of their experience when they are engaging in it (Hektner, Schmidt, & Csikszentmihalyi, 2006). Two good examples of the use of this method for investigating music listening motivations in everyday life are studies conducted by Dillman et al., (2008) and also Västfjäll, Juslin and Hartig (2012).

Research has indicated that music listening has a positive effect on health, but especially positive emotional experience during music listening (Västfjäll, Juslin, & Hartig, 2012). In order to not cause any confusion about the interpretation of our results, we emphasise here that the aim of our study has not been to prove that listening to SISM is a good strategy to achieve mood-enhancement, or that mood-enhancement is the main reason for listening to sad music. Results of our continuous study have rather indicated opposite results. More specifically, listening to sad music when feeling sad will intensify feelings of sadness for most people (Van den Tol, 2011, 2012, Van den Tol and Edwards, 2011, 2012, Under review). Similarly, recent results by Garrido and Schubert (2013) have indicated that many people feel sad rather than happy after having listened to self-selected sad music. It has to be noted, however, that when people listen to music in order to be in touch with emotions, experiencing sad emotions is not always reported as a negative event by the individual (Schubert, 2007). Some people describe expressing and being in touch with sadness during music listening as a cathartic experience (Van den Tol & Edwards, 2011).

Some people are better able to enjoy sad music and experience positive emotions during sad music listening to a greater extent than other people (Garrido & Schubert, 2013). Recent research indicates that people's ability to move on from sad thoughts is especially impaired among ruminators, whereas ruminators' use of sad

LISTENING TO SAD MUSIC

music is more maladaptive than that of other people (Garrido & Schubert, 2013). These findings suggest the importance of more research that explores people's motivations for listening to SISM while simultaneously exploring complimentary temporal factors. Indeed, Chen, Zhou, & Bryant, (2007) indicated that temporal factors are important to acknowledge to understand people's music listening behaviour. Research that relates music listening behaviour to psychological health is especially important as it will provide valuable information for music therapists and other professionals working in (mental) health care (Edwards, 2011).

LISTENING TO SAD MUSIC

TABLES

Table 1: *Rotated Component Matrix on Direct Goals*

	Components				
	1	2	3	4	5
1= Sadness					
2=Memories and Social					
3= Friendship					
4=Cognitions					
5=Distraction					
<hr/>					
The reasons I listened to the sad music was...					
...to bring back memories		0.70			
...to remind me of people I know		0.79			
...to remind me of people that have passed away		0.87			
...to feel connected to people I know		0.64			
...to feel a connection with people that have passed away		0.83			
...to get in touch with my emotions and thoughts	0.74				
... to enter into a safe place where I can get away from my problems					0.54
...to distance myself from the problem					0.84
...to focus my attention on something else					0.70
...to release my emotions		0.80			
...to make me experience emotions related to my life's circumstances		0.74			
...to cry		0.73			
...to grieve		0.61			
...to express my feelings and thoughts		0.64			
...to strengthen my emotions		0.66			
...to see things from a different perspective					0.68
...to get a more realistic view of my feelings and thoughts					0.75
...to better understand whatever situation I am in					0.71

LISTENING TO SAD MUSIC

...to really experience and express my emotions in the hope that I can then move on	0.61
...to feel understood	0.73
...to feel like I am being empathized with	0.85
...to feel befriended by the music	0.74
...to feel less alone	0.65

Note: The eigenvalues of the rotated principal component analyses for direct goals ranged from 4.71 on the first component to 2.05 on the fifth component. The five components of direct goals explained 68.67 of all variance in the data.

LISTENING TO SAD MUSIC

Table 2: *Rotated Component Matrix on Direct Effects*

	Components				
	1	2	3	4	5
1=Sadness					
2=Memories and Social					
3= Friendship					
4=Distraction					
5=Cognitions					
Listening to this sad music did....					
...bring back memories		0.61			
...remind me of people I know		0.77			
...remind me of a someone that passed away		0.86			
...make me feel connected to people I know		0.68			
...make me feel connected to people that have passed away.		0.81			
... make me in touch with my emotions and thoughts	0.73				
... provide a safe place where I could get away from my problems				0.65	
... make me distance myself from the problem				0.83	
... make me focus my attention on something else				0.77	
...make me release my emotions	0.80				
...make me experience emotions related to my life's circumstances	0.76				
...make me cry	0.73				
...make me grieve	0.65				
...make me express my feelings and thoughts	0.74				
...make my emotions stronger	0.69				
...make me see things from a different perspective					0.61
...make me get a more realistic view at my feelings and thoughts					0.76
...make me better understand my situation					0.77
...make me strongly experience and express my emotions, making them wear off	0.63				
...make me feel understood			0.65		
...give me the feeling like the music is empathising with me			0.65		

LISTENING TO SAD MUSIC

...make me feel befriended with the music	0.74
...make me feel less alone	0.60

Note: Eigenvalues of the rotated principal component analysis for direct effects ranged from 5.19 on the first component through 2.27 on the fifth component and explained 66.90 percent of variance in total.

LISTENING TO SAD MUSIC

Table 3: *Rotated Component Matrix on Indirect Goals*

Component 1 =Mood Enhancement	1
The reasons I listened to the sad music was....	
...to feel good	0.66
...to calm me down	0.65
...to make me feel better	0.71
...to be cheered up	0.83
...because it has a soothing effect on me	0.82

Note: The eigenvalue on the only rotated component on the principal component analyses on indirect goals was 3.20 and explained 64.01 of all variance.

LISTENING TO SAD MUSIC

Table 4: *Rotated Component Matrix on Indirect Effects*

Component 1 =Mood Enhancement	1
Listening to this sad music did...	
...make me feel good	0.84
...make me feel better	0.79
...cheer me up	0.83
...calm me down	0.84
...have a soothing effect on me	0.72

Note: The eigenvalue on the only rotated component on the principal component analyses on indirect goals was 3.20 and explained 64.01 of all variance.

LISTENING TO SAD MUSIC

Table 5: *Rotated Component Matrix on Music Selection Strategies*

1= Direction 2= Memory Triggers and Connection 3= High Aesthetic Value	Component		
	1	2	3
I choose to listen to the music because ...			
... the music brings back memories		0.67	
... the music is music that reminds me of a person		0.82	
... the music has as a useful message	0.60		
... the music contains lyrics that communicate hope	0.95		
... the music contains lyrics that communicate a positive message	0.84		
...to experience the beauty of the sad songs			0.95
...to experience the beauty of the sad lyrics			0.81
...because I love sad music in general			0.61
...because the lyrics relate to my situation		0.64	
...because the mood of the music is similar to my own mood		0.51	

Note: The rotated components eigenvalues for strategies ranged from 2.12 on the first component to 2.06 on the third component, the component outcome of all strategies components cumulatively explained 62.86 of all variance in the data, with the first component explaining 21.15 percent and the third 20.64.

LISTENING TO SAD MUSIC

Figure 1: A Graphical Representation of the Parallel Mediation Analyses that Were Conducted in Order to Investigate How Listening to SISM (is Expected to) Result(s) in Mood Enhancement.

Note: 4 out of 8 analyses were conducted with the recalled effects as parallel mediator. The other 4 analyses were conducted with the identified goals. In all the analyses 1 of the 4 identified music selection strategies were selected as the independent variable and mood enhancement was the dependent variable.

FOOTNOTES

¹ Please note that the second aim of this paper focussed on investigating: *Why do people use certain music selection strategies*. More specific, this aim focussed on how effective the use of a specific music selection strategy are is for achieving a certain specific self-regulatory goals or reported effects (focus on one strategy). Another (different) aim could be: Understanding which music selection strategies would be *most commonly used* or *most effective* in order to achieve certain specific self-regulatory goals or reported effects (focus on comparing multiple strategies). Please note that for the aim that we discussed for this paper we focussed on understanding the value of each specific music selection strategy. Simple regression analysis can be used (with one predictor and one independent variable) for this aim. The focus of the different aim would have been comparing multiple strategies. For the latter (different) aim a series of regression analyses would have been required with several music selection strategies as predictors and one goal or effects as a dependent variable. For the brevity of this paper we did not include the latter analysis, however results of this analysis can be send on request.
